Received and published: 29 April 2013

An amount of magma is produced following mantle decompression and it is admitted into a magma chamber. Equal amount of magma is consumed at midocean ridges. A large magma chamber having a large residence time acts as a bladder whose volume does not vary substantially with small variations of magma flow rate. As a result, the pressure in the magma system can be assumed to remain steady at any elevation. This provides steady and sustained pressure that drives the tectonic plates. Please see lines 15-25 of page 140 of the manuscript.
