The work reveals new significant data on micromorphological composition of postfire soils. Soil cover of Tol'yatti city has been significantly altered due to catastrophic fires in 2010 and resulted in formation of pyrogenically transformed soils. The results obtained expand the scope of understanding of pyrogenic soils and their physical and chemical properties. In my opinion more analytical data on soil physical and chemical properties have to be added for the text body of the manuscript to achieve more evident connections with micromorphological characteristics.
