Reply to Anonymous referee

Dear Prof. Roberts and anonymous referee,

thank you very much for your input on the manuscript. Here is our response to your comments. We hope that the changes we implemented improve the shortcomings of the manuscript highlighted by your comments and suggestions. Please do not hesitate to contact us shall this not be the case for some of your comments.

1. Comments from the referees and Topical Editor

Comments from anonymous referee

Comment 1: the text is excessively long and could reasonably be expected to be shorted to make the salient points more accessible to the readership.

Comment 2: The ages are distinct from other high temperature and Ar/Ar texturally constrained results from Finnmark which illustrate the importance of Caledonian processes. Much better evaluation of the results in the context of these other geochronometers is needed. Specifically, why are the ages so different, is it simply due to different fabrics being dated, a different closure temperature of the system and mineral, or are secondary alteration processes at play? It is trivial to address this question but is needed to place the work in the current regional context. The reported ages may very well be correct but then more detail is required to put them in the context of post Caledonian process (in the main).

Comment 3: More evidence is required to demonstrate that the clay minerals all formed at the same time and that they have not been subsequently modified with later fluid movement on the "dated" structures. For example, more SEM and EBSD textural work would be a distinct advantage in addressing how many different fabrics are associated with each of the sampled structures.

Comment 4: What is the potential of fine fraction feldspar modifying the K/Ar results? Is there evidence of significant fluid alteration on these structures?

Comment 5: I am somewhat concerned with the number of references to unpublished works that are cited as "submitted" (e.g. Koehl et al., Davids et al.,). I do not think it acceptable to heavily rely on such currently unpublished work so I would suggest that a summary of the salient points in those unpublished works is presented in this paper so all the evidence for statements in this work is available to readers.

Comment 6: Line 16: sentence structure I think you mean "during the opening of": : :. Line 34: replace "which" with "whose".

Comment 7: Line 50; you probably should mention the timing of collisional phases as constrained this region prior to discussing post-Caledonian extension. See Kirkland et al., 2006, The structure and timing of lateral escape during the Scandian Orogeny: A combined strain and geochronological investigation in Finnmark, Arctic Norwegian Caledonides, which discusses the constraint on the timing of the collisional phase (431-428 Ma).

Comment 8: Line 65: you need to present the evidence or at least discuss (if it is already published) the evidence for Timanian deformation in northern Finnmark.

Comment 9: More discussion on the rational for a 30'c/km geotherm is needed. There are some regional thermobarometry studies that point to the peak P-T conditions which may be relevant assist in placing constraints on the retrograde thermal pathway.

Comment 10: There are some sections of the text that need rewritten, for example evaluating the results against an unpublished (e.g. submitted) model (e.g. TKFZ development) by the same authors and coming to the conclusion that the previous unpublished model is wrong seems odd to me. You already know it doesn't work with your data.

Comment 11: Line 105-115; I would have thought it relevant to discuss the results on basement metamorphism as provided by pseudosection thermobarometry, as it is likely to be some of the most accurate P-t constraints in the region and at least provides some constraints for subsequent processes. â˘A ´c Gasser et al., 2015; D. Gasser, P. Jeˇrábek, C. Faber, H. Stünitz, L. Menegon, F. Corfu, M. Erambert, M.J. Whitehouse Behaviour of geochronometers and timing of metamorphic reactions during deformation at lower crustal conditions: phase equilibrium modelling and U–Pb dating of zircon, monazite, rutile and titanite from the Kalak Nappe Complex, northern Norway. â˘A ´c Kirkland et al., 2016: C.L. Kirkland, T.M. Erickson, T.E. Johnson, M. Danišík, N.J. Evans, J. Bourdet, B.J. McDonald, Discriminating prolonged, episodic or disturbed monazite age spectra: An example from the Kalak Nappe Complex, Arctic Norway, Chemical Geology, Volume 424, 2016, Pages 96-110.

Comments from Prof. Roberts

Comment 1: Page 1, and throughout the ms. The temporal adjectives Early, Mid and Late should be capitalised (e.g., Mid Neoproterzoic). The authors are inconsistent on this point.

Comment 2: Several pages. Composite adjectives should be hyphenised, e.g, greenschist-facies rocks, but not when writing . . . The rocks were metamorphosed in greenschist facies.

Comment 3: Page 1, line 12 (also p.9, line 273 and p. 10, line 286). The correct term is 'Raipas Supergroup' (there are several groups within the Raipas Supergroup).

Comment 4: Page 2, line 53. Write Late Devonian. Then add reference to Guise & Roberts 2002 (NGU Bulletin).

Comment 5: Page 3, line 67. ” : : :..fault complex, the age of which is yet uncertain (Zw. . . .”. Then on line 69 ” . . . onto the eastern Finnmark Platform where : : :” Next, on line 87 ”cross-cutting”.

Comment 6: Page 4, line 102. After 1983, add reference to Torgersen et al. 2015Âÿ NJG Vol 95. Then, after 1985, add reference to the classical paper by Gayer et al. 1987, Trans.Royal Soc.Edinburgh. Note the spelling of Ramsay, not Ramsey.

Comment 7: Page 4, line 104. Elvevold was not the first to write about the SIP. Many publications by Robins and students/colleagues. Here you can add Robins & Gardner 1975, Earth Planet.Sci.Letters 26. Page 4, Line 105. Again, Robins should be mentioned, in front of Corfu. Add Robins 1998, Geol. Mag. 135, 231-244.

Comment 8: Page 4, Lines 108-110. Here you need to achieve a balance between the two main interpretations for the Kalak. In line 108, write . . . ” . . .is thought by some workers to represent . . .”. Then, add a new sentence after (Kirkland et al. 2008). ”However, others have provided robust evidence for a Baltican origin (e.g., Roberts & Siedlecka 2012, Zhang et al. 2016).”

Comment 9: Page 4, line 111. ”to amphibolite-facies . . . . composed of psammites, . . . ” (Note – psammites are metamophosed sandstones, so the prefix ’meta’ is not required.). Then on line 112, Ramsay, not Ramsey. On line 113, add Robins & Gardner 1975 before Elvevold. On line 118, add Robins 1998 before Corfu.

Comment 10: Page 5, line 125. You should add Lippard & Roberts 1987 before Bergh.

Comment 11: Page 5, line 142. Should Nasuti et al. 2015 be 2015a ? Line 149, shows not show; then on line 150 thrusts not thrust.

Comment 12: Page 6, line 156. ” . . .are juxtaposed against amphibolite-facies . . . ” Then, line 174 ” compositions and with the results of . . .” On line 180, ”brittle faults that we encountered . . .”

Comment 13: Page 7, line 193. The Ksienzyk reference is not in the References. The very last word on this line should be ’whose’, not which.

Comment 14: Page 7, lines 206-207. ”have been shown to be a sensitive . . . . . .low-grade . . .” Then, the end of this sentence . . . . . ”in clastic sedimentary rocks.” These are not unconsolidated sediments but lithified sedimentary rocks.

Comment 15: Page 8, line 230. ”Synkinematic illite commonly grows . . .” Do not use adverbs of time in cases like this – e.g often, frequently, occasionally. There are many such examples in this manuscript. Line 242, ” . . thus causing coarse fractions . . . ” Line 245 ” and, thus, yield rebust . . . .”

Comment 16: Page 9, line 247. contrary, not contrarily. Next line . . . . ”is unlikely”. Next line temperatures. Line 256, counterparts should be one word. Line 272 Raipas Supergroup. Also on next page, line 286.

Comment 17: Page 10, line 294. ”accommodated a vertical displacement of >5-6 m.” Line 305/6 ”The northern fault accommodates . . .”

Comment 18: Page 11, line 310 ”Along strike to the northeast, we . . .” Line 312 ”that cross-cuts arkosic psammites . . ” Line 313 replace ”made” by the word composed

Comment 19: Page 11, the subheading 4.1.3. This is incorrect and misleading. These brittle faults are nowhere near the TKFZ. Rephrase as follows – ”Brittle faults on Porsanger Peninsula and Magerøya (samples 8, 9 & 10)”

Comment 20: Page 12. The very first sentence (lines 338-340) needs some rewriting, as follows – ” are widespread in the Kalak Nappe Complex on the Porsanger Peninsula and in the Magerøy Nappe on the island of Magerøya (Figure 1; cf. Koehl et al., in prep.).” This Koehl et al manus has NOT been submitted to NJG, at least not received by the editor (I have checked this). Line 343, ”Magerøy Nappe rocks on . . .” Line 348, ”Farther north, on Magerøya, sample 9 corresponds . . .”

Comment 21: Page 13, line 385. ” . . . /metavolcanites, gabbros and mica schists.” Line 397, ” is composed of”

Comment 22: Line 398 ” , commonly reworked . . .”

Comment 23: Page 14, line 400. ” In places, epidote-chlorite-bearing ”

Comment 24: Page 15, line 437. ” is composed of . . . ” Line 458, part of this sentence is unclear —” younger age in tendency compared to ..”. Authors please note: ”compare to” means to liken one thing to another, whereas ”compare with” indicates that one wishes to show the differences between one thing and another.

Comment 25: Page 16, line 477. Delete the words ”along the TKFZ” ! Lines 478-481, In this sentence (and in several other sentences in the ms) you give what you say are three ”ages” for the different fractions. These are just numbers or dates. You then have to interpret them as real ages of mineral-forming events.

Comment 26: Page 17, line 499. Delete the words ”segment of the TKFZ”. Line 502, ”suggesting that the fault . . .” Line 507, ”associated with the ”

Comment 27: Page 18, line 522. ” hence yielding ages younger than the actual age of faulting . . .” Lines 535-36, ”However, a minor . . . . . spectra of all . . . . . .suggests that the. . . .”

Comment 28: Page 19, line 576, ” . . . 3c). Subsequently, basement rocks were exhumed to a shallow . .. ”

Comment 29: Page 21 , lines 623/4. Do not use Ma here. Instead write . . . . ”10-75 m per mill. yrs.” and later, ”10-100 m per mill. yrs.” This crops up at many other places in the ms.

Comment 30: Page 22, line 652. ”at depths between 3 and 10 km.” Line 662, ”along fault segments of the LVF and faults parallel to the TKFZ, showing . . . .”

Comment 31: Page 23, line 676, ”suggesting that the dominant . . . ” Line 683 ”WNW-ESE-trending faults associated with the” Line 691 ”along the LVF and parallel to the TKFZ . . .”

Comment 32: Page 24, line 711, ”earliest indications of . . .” Line 717 ”Silurian age may reflect input from an inherited” Line 733 ” of the LVF and faults parallel to the TKFZ outlined . . .” On next page, line 743, Koehl et al., in prep.

Comment 33: Page 26, line 777, ” at shallow depths between 1 and 3.5 km . . .”

Comment 34: Page 27, lines 816/17, ”although quite commonly associated with large amounts of chlorite along fault segments of the LVF (e.g., the Talvik fault and the Sørkjosen faults . . .”

Comment 35: Page 28, line 831 ” . . analyses of gouge from a fault parallelling the TKFZ in . . .” Line 839, ”indicating that exposed rocks in northern . . .” Line 856, ”erosion with only a limited . . .”

Comment 36: Page 29, line 880, ”A reliable Mesozoic K/Ar age was obtained only for the . . . ”

Comment 37: Page 30, line 887 Spelling . . . scarcity, not scarsity Line 898 in prep. , not submitted Line 906, ”conjugate strike-slip faults have been reported from NW Finnmark . . . .” Line 908 This statement is incorrect. The Timanian contraction in the Late Neoproterozoic was directed towards the SW, not along the strike of the orogen.. This has been described in numerous publications.

Comment 38: On pages 31, 32 & 33 I have noted dozens of small errors; these will surely be picked up by the editor.

Comment 39: Page 38, lines 1151-53, The area covered by this forthcoming manuscript (NOT yet submitted) seems to be comparable to that of the present contribution. How much repetition will there be, one wonders? But perhaps the authors will be describing completely different faults? – and taken mostly from the theses of E.Bergø and H.Lea ?

Comment 40: The results are very interesting and only the second such study of dating mineral growth in gouges and cataclasites in the northwestern part of Finnmark. Many numbers/dates are given, for the three different grain-size fractions, so it is up to the authors to explain why they interpret every single number as a true age. The authors mention just ”illite”, sensu lato, but there are several polymorphs of illite, e.g., 1M, 1Md and 2M1, so do they know for sure which polymorph they have been analysing?

Comment 41: All the figures appear reasonable and acceptable, except for the incorrect placing of the TKFZ in Figure 1 and Figure 4. This error MUST be corrected. I have corresponded with the first author on an earlier occasion about this matter (in another paper of his in Solid Earth), so he knows the facts. The TKFZ is described and defined from the Varanger Peninsula, just outside the eastern limits of Figures 1 and

4, but continues WNWwards through the isthmus on the south side of the Nordkinn Peninsula (marked as NP in Figures 1 and 4). That is where the authors should write in the acronym TKFZ (in smaller capital letters).

Comments from Topical Editor Bernhard Grasemann

Comment 1: I think the manuscript is now ready for publication after some very minor points raised by the reviewer.

Comment 2: I also agree with the reviewer that there are too many unpublished papers referenced and at least "submitted" or "under review" should be deleted.

Comment 3: Additionally, the field pictures in Figure 2 and thin sections in Figure 3 need exact location descriptions or better GPS coordinates

2. Author's response

Response to comments from anonymous referee

Comment 1: Agreed.

Comment 2: The correlation with other high-temperature chronometers is clear, as they are dealing with higher closure temperatures (U–Pb in zircon, or K–Ar and Ar–Ar in muscovite), the data we present simply have to be younger. K–Ar and Ar–Ar cooling ages on biotite are of special interest, because they are interpreted to reflect the cooling below 300°C (McDougall & Harrison, 1999). This temperature marks the transition from ductile to brittle deformation (Tullis & Yund, 1977; Scholz, 1988; Hirth & Tullis, 1989). Therefore, oldest fault gouge ages could be in the range of biotite cooling ages, but should never be older. For example, we obtained one Silurian age (427.3 ± 8.4 Ma) representing either mixing with host-rock (inherited muscovite/illite) or Silurian brittle faulting. Based on the dominant transport direction and kinematics along the Talvik fault (dip-slip top-south), we propose that the Silurian age reflects continued thrusting rather than lateral escape (as proposed in Kirkland et al., 2006 for orogeny-oblique thrusts). This age is consistent with U–Pb ages on titanite and pseudosection thermobarometry of Gasser et al. (2015) constraining Caledonian retrograde shearing at temperature < 550°C to Silurian times (440-420 Ma). To carry out investigations on other low-temperature chronometers like U–Th/He dating or fission track is beyond the scope of this manuscript, which rather focuses on the structural framework.

As fault gouges are the weakest point in the crust, they are often reactivated by ongoing deformation. This can lead to repeated growth of clay mineral, yielding significant ages in different grain fractions or to

meaningless mixing ages. Secondary alteration processes are unlikely as clay minerals are very stable in the shallow crust, but can never be excluded.

The context of post-Caledonian processes as been widely discussed by several authors, onshore and offshore (e.g., Davids et al., 2013; Gudlaugsson et al., 1998; Indrevær et al., 2013; Torgersen et al., 2014; Ksienzyk et al., 2016).

Ksienzyk, A.K., Wemmer, K., Jacobs, J., Fossen, H., Schomberg, A.C., Süssenberger, A., Lünsdorf, N.K. & Bastesen, E. 2016. Post-Caledonian brittle deformation in the Bergen area, West Norway: results from K–Ar illite fault gouge dating, Norwegian Journal of Geology, 96, 1-29.

McDougall, I. & Harrison, T. M. 1999. Geochronology and Thermochronology by the 40Ar**/**39Ar Method, 2nd Oxford University Press, New York.

Scholz, C. H.: The brittle-plastic transition and the depth of seismic faulting, Geologische Rundschau, 77/1, 319-328, 1988.

Torgersen E., G. Viola, H. Zwingmann and C. Harris. 2014. Structural and temporal evolution of a reactivated brittle-ductile fault – Part II: Timing of fault initiation and reactivation by K-Ar dating of synkinematic illite/muscovite. Earth Planet. Sci. Lett., vol. 407, pp. 221-233.

Tullis, J. and Yund, R. A.: Experimental deformation of dry Westerly Granite, Journal of geophysical Research, 82, 36, 5705-5718, 1977.

Comment 3: It would be nice to have all kinds of accompanying investigations, but this is not the focus of our studies. The overwhelming majority of fault gouge papers in literature is accepted without SEM and EBSD work.

Comment 4: The influence of older feldspar leading to younger ages by the low closure temperature has been explained in the text. A significant fluid alteration of feldspar in the fault gouge structure would lead to the formation of sericite, which in many cases can be recognized easily by a well-crystallized 001-white mica peak. We did not find any indication for this in our x-ray patterns.

Comment 5: The work by Davids et al. submitted is only briefly integrated to the study for comparison purposes and the conclusions of the present manuscript do not rely at all on the conclusions of Davids et al. submitted. Regarding the Koehl et al. (submitted) work, it is already available on Researchgate and on the data repository of the University of Tromsø as part of the PhD thesis of the main author (Koehl, 2018; paper 1). Thus, we find it acceptable to refer to this earlier work.

Koehl, J-B. P.: Mid/Late Devonian-Carboniferous extensional faulting in Finnmark and the SW Barents Sea, Unpublished PhD Thesis, University of Tromsø, Norway, 2018.

Comment 6: Agreed.

Comment 7: Agreed.

Comment 8: Agreed.

Comment 9: Agreed. See answer to comment 11.

Comment 10: We do not know whether the model presented in Koehl et al. (submitted; Norwegian Journal of Geology) is wrong or right. However, we hereby present an alternative to this model and try to be critical with our own work. We believe that mentioning the model presented in Koehl et al. (submitted) is important to the follow up of the that study, and does not impede the clarity of the present contribution.

Comment 11: Agreed for the Gasser et al. (2015) study. However, we do not think the proposed work of Kirkland et al. (2016) is suitable to discuss the exhumation of Paleoproterozoic basement rocks in Finnmark because the samples dated in this study are from younger rocks of the Kalak Nappe Complex. This work is not appropriate either to discuss the exhumation history of Caledonian rocks during post-Caledonian extension because the ages obtained are pre-Caledonian and do not yield any information about peak Caledonian metamorphism.

Response to comments from Prof. Roberts

Comment 1: The temporal adjective should exclusively be capitalized when referring to an actual Stage or Period. However, this is not the case of early, mid and late Neoproterozoic, which official names on the

Geological Time Scale 2012 are Tonian, Cryogenian and Ediacaran respectively. The same goes for early and late Carboniferous, which formal names are Mississippian and Pennsylvanian. On the contrary, Early, Middle and Late Devonian should be capitalized.

Comment 2: Agreed.

Comment 3: Agreed.

Comment 4: Agreed. However, we believe that the addition of "Late" ahead of "Devonian" is not needed since it is still debated when post-Caledonian extension initiated in the northern Norway, (e.g., Steltenpohl et al., 2011; Koehl et al., 2018).

Comment 5: Agreed.

Comment 6: Agreed. Unfortunately, we cannot include the suggested "Gayer et al. 1987" publication, because this scientific contribution is not accessible to the authors of the present manuscript. Moreover, the reference does not significantly improve the manuscript.

Comment 7: Agreed.

Comment 8: Agreed.

Comment 9: Agreed.

Comment 10: Agreed.

Comment 11: Agreed for "thrust" and "show". However, only one Nasuti et al. (2015) study is used as supporting literature in the present manuscript and it is therefore not necessary to change reference to "Nasuti et al., 2015a".

Comment 12: Agreed.

Comment 13: Agreed.

Comment 14: Agreed.

Comment 15: Agreed.

Comment 16: Agreed.

Comment 17: Agreed.

Comment 18: Agreed.

Comment 19: Recent work (Koehl, 2018; Koehl et al., 2018; Koehl et al., submitted) interpret margin-oblique, WNW-ESE striking brittle faults on the island of Magerøya as fault segments of the Trollfjorden-Komagelva Fault Zone. Thus, we prefer to leave subheading 4.1.3 as it is now.

Comment 20: Agreed that the sentence needs rewriting but not as suggested. The rewriting suggested by the referee does not reconcile the occurrence of units belonging to the Magerøy Nappe on the Porsanger

Peninsula (Gasser et al., 2015). The authors agree with all the other remarks in comment 20 and updated the manuscript accordingly.

Comment 21: Agreed.

Comment 22: Agreed.

Comment 23: Agreed.

Comment 24: Agreed.

Comment 25: Agreed. The data presented is called “ages” because they were calculated from isotopic ratios generated by radioactive decay. The discussion has to specify the interpretation of the age, whether it is crystallization, recrystallization, cooling or a geologically meaningless mixing age.

Comment 26: Disagree with the referee’s comment based on work by Koehl et al. (in review, Norwegian Journal of Geology). This work interprets WNW-ESE striking faults on Magerøya as fault segments of the TKFZ. The authors agree with the other remarks of the comment.

Comment 27: Agreed.

Comment 28: Agreed.

Comment 29: Agreed.

Comment 30: Agreed with the first remark but not with the second one (again see Koehl et al., 2018, submitted and Koehl, 2018)

Comment 31: Agree with first remark, but disagree with last two remarks (cf. Koehl et al., 2018, submitted and Koehl, 2018).

Comment 32: Agreed. However, the authors do not agree with the last two remarks: the work by Koehl et al. is now submitted to the Norwegian Journal of Geology and is currently being reviewed.

Comment 33: Agreed.

Comment 34: Agreed.

Comment 35: Disagree with first remark (cf. Koehl et al., submitted, also in Koehl, 2018), but agree with last two remarks.

Comment 36: Agreed.

Comment 37: Agreed.

Comment 38: Agreed.

Comment 39: The manuscript referred has now been submitted. Potential repetition in the other manuscript do not affect the review process of the present manuscript. Most faults from Lea 2016 and Bergø 2016 discussed with different perspectives than in Koehl et al. (submitted).

Comment 40: Agreed. Analytical data presented here as ages cannot be treated like high-precision ages from e.g., modern U-Pb zircon dating. Our ages point to a time interval, which can be in some cases much larger than the analytical error given in the 2-σ error interval. We have to add this statement in the beginning of the discussion. Indeed, it would have been a great help for interpretation to identify and quantify the amounts of illite-polytyps 1Md, 1M and 2M1. However, since the mineralogical composition is dominated by smectite and chlorite the specific peaks for the polytyps are not recognizable due to peak overlap.

Comment 41: Agreed.

Response to comments from Topical Editor Bernhard Grasemann

Comment 1: Agreed.

Comment 2: Disagree. The present manuscript contains references to only one unpublished paper (Davids et al., in review in Terra Nova). As already mentioned in our response to Prof. Roberts and the anonymous referee, the "Koehl et al. (submitted)" article is already published as part of the main author's Ph.D. thesis and freely accessible at munin.uit.no/handle/10037/13021 and at www.researchgate.net/profile/Jean-Baptiste_Koehl/publications. We agree that referencing unpublished work is not ideal for a journal, but as soon as the referenced unpublished work is published, there is always the possibility for other scientists/researchers to follow up by writing a comment to the present manuscript.

Comment 3: Agreed.

3. Changes implemented

Changes based on comments from anonymous referee

Comment 1: Removed "cf." trough manuscript (23 occurrences); changed "top-to-the- " expressions to "top- " consistently through the whole manuscript ; deleted "Caledonian" line 717; deleted "/age" line 722; changed "top-to-the-south, brittle (-ductile?), Caledonian" to "top-south Caledonian brittle" line 722; deleted fault orientation, e.g., "NNE-SSW striking", lines 332, 340, 353, 365-366, 1424, 1425-1426, 1427, 1429, 1430, 1435, 1437.

Comment 2: see answer to comment 11. Added Tullis & Yund (1977), Gasser et al. (2015) and Ksienzyk et al. (2016) to reference list.

Comment 3: none.

Comment 4: none.

Comment 5: none.

Comment 6: changed “which” by “whose” line 34.

Comment 7: added “Near the end of Caledonian contraction, lateral escape initiated in a NE-SW direction, and this episode of deformation was constrained to ca. 431–428 Ma by U–Pb and Ar–Ar dating (Kirkland et al., 2005, 2006; Corfu et al., 2006)” lines 51-53, and Kirkland et al. 2006 to the reference list.

Comment 8: added “Siedlecka & Siedlecki, 1967; Roberts, 1972; Siedlecka, 1975” as supporting literature for Timanian deformation in northern Finnmark.

Comment 9: see answer to comment 11. Also, we added the following references to support the choice of a 30°C/km geothermal gradient: Bugge et al., 2002; Chand et al., 2008; Vadakkepuliyambatta et al., 2015.

Comment 10: none.

Comment 11: added “U–Pb ages on titanite from northern Troms provide a minimum estimate of ca. 440–420 Ma for retrograde (< 550°C) Caledonian shearing (Gasser et al., 2015)” line 108-110, and Gasser et al. 2015 to reference list. Also added “, which is consistent with pseudosection thermobarometry and U–Pb ages on titanite constraining retrograde Caledonian shearing < 550°C (i.e., < 18 km depth) in the Kalak Nappe Complex in northern Troms to 440–420 Ma (Gasser et al., 2015)” in discussion chapter, line 655-657 and “This is consistent with thermobarometry and U–Pb ages constraining Caledonian retrograde shearing at temperature < 550°C to the Silurian at ca. 440 –420 Ma (Gasser et al., 2015).” lines 728-730.

Changes based on comments from Prof. Roberts

Comment 1: none.

Comment 2: hyphenized “greenschist-facies” through manuscript where needed (eight occurrences).

Comment 3: changed “Raipas Group” to “Raipas Supergroup” three times through manuscript.

Comment 4: added “Guise & Roberts, 2002” in main text and to the reference list.

Comment 5: changed as suggested by referee. Also changed “Finnmark Platform east” to “eastern Finnmark Platform” lines 140 and 149, and “Finnmark Platform west” to “western Finnmark Platform”.

Comment 6: added reference to Torgersen et al. (2015a) line 105 and to reference list. Changed other reference to “Torgersen et al. (2015)” to “Torgersen et al. (2015b)”. Corrected “Ramsey” to “Ramsay” (two occurrences)

Comment 7: added following references to the main text and reference list: Robins and Gardner (1975); Robins (1998).

Comment 8: added “by some workers” line 113. Also added “However, others have provided robust evidence for a Baltican origin (Roberts, 2007; Zhang et al., 2016)” lines 115-116, and both references (Roberts, 2007; Zhang et al., 2016) to reference list.

Comment 9: changed “meta-psammite” and “meta-psammitic” to “psammite” and “psammitic” respectively (four occurrences in main text).

Comment 10: added suggested reference line 132.

Comment 11: changed “show” into “shows” line 156 and “thrust” into “thrusts” line 157.

Comment 12: changed “with amphibolite facies” to “against amphibolite-facies” line 163 and “zeolite facies” and “prehnite-pumpellyite facies” to “zeolite-facies” and “prehnite–pumpellyite-facies” (multiple occurrences). Also changed “composition and with the result” to “compositions and with the results” line 181, and added “that” line 187.

Comment 13: added Ksienzyk et al., 2016 to reference list and changed “which” to “whose” line 200.

Comment 14: added “been” and changed “low grade” to “low-grade” line 214, and changed “sediments” to “sedimentary rocks” line 215.

Comment 15: changed “often” to “commonly” lines 137, 237, 387, 408, 415, 433, 441, 575, 668, and 688; replaced “often” by “generally” line 420 and 839; changed “occasionally” to “in places” line 410 and 577; changed “are commonly undeformed and often appear” into “commonly are undeformed and appear” line 684; deleted “often” line 389; changed “leading” to “causing” line 249; replaced “provide with” by “yield” line 252.

Comment 16: changed “contrarily” to “contrary” line 254; changed “are” into “is” line 255; changed “temperature” to “temperatures” line 256; changed “counter-parts” to “counterparts” line 266.

Comment 17: changed sentence to “The northern fault accommodates” line 315-316.

Comment 18: changed “northeastward” to “to the northeast” line 320; changed “crosscuts” to “cross-cuts” line 322; replaced “made” by “composed” line 323.

Comment 19: none.

Comment 20: changed sentence to “are widespread within units of the Magerøy Nappe on the Porsanger Peninsula and on the island” lines 348-349. However, changed “unit” to “rocks” as suggested by the referee line 353. Also added “on Magerøya, ” line 358, and referece to “Robins, 1998” line 360.

Comment 21: changed “metavolcanics” to “metavolcanites” and “micaschists” to “mica schists” line 396, and “made” into “composed” line 408.

Comment 22: changed “often” into “commonly” line 409.

Comment 23: sentence updated to “In places, epidote–chlorite-bearing” line 411-412.

Comment 24: changed “made” to “composed” line 450; deleted “in tendency” and changed “compared to” to “compared with” line 471.

Comment 25: changed sentence line 477 to “Most dated fault gouges from segments of the LVF and TKFZ in the Kalak Nappe Complex and Magerøy Nappe on the Porsanger Peninsula and Magerøya yielded late Paleozoic ages”; Also added “, and we interpret them both as syn-kinematic crystallization along an active normal fault“ lines 468-469; “syn-kinematic crystallization of authigenic illite during” lines 480-481; “are interpreted as syn-tectonic crystallization ages and” line 491; “syn-kinematic crystallization” lines 495-496; “These syn-kinematic crystallization ages suggest” line 506; “, which we all interpret as syn-tectonic crystallization ages. These ages suggest that” lines 513-514; “The ages obtained for the coarse and fine fractions are interpreted to represent syn-kinematic crystallization of authigenic illite.” Lines 525-527; “syn-kinematic crystallization during” line 533; “, which we interpreted as syn-kinematic crystallization ages” lines 603-605 ; “, which we interpreted as crystallization ages” line 610; “crystallization age of” lines 732-733; “and interpreted as syn-kinematic crystallization ages” line 744; “syn-kinematic crystallization” lines 755-756; “syn-tectonic crystallization” line 774; “syn-kinematic crystallization” line 780; “syn-kinematic crystallization” line 863; “syn-tectonic crystallization” line 904.

Comment 26: added reference to “Koehl et al., submitted” lines 514-515. Also changed “to” into “with” line 523.

Comment 27: changed sentence line 539 to “hence yielding ages younger than the actual age”, and line 553-554 to “However, a minor K-feldspar content observed in the diffraction spectra of all three grainsize fractions of both of these faults suggests that the” as suggested by the referee.

Comment 28: changed “Then” to “Subsequently” line 596, and added “a” line 397.

Comment 29: changed “Ma” into “Myr” (multiple occurrences through manuscript).

Comment 30: changed sentence line 676 to “at depths between 3 and 10 km”.

Comment 31: added “that” line 700.

Comment 32: replaced “evidence” by “indications” line 735; changed sentence line 743 to “Silurian age may reflect input from an inherited”.

Comment 33: changed “–“ to “and”.

Comment 34: changed sentence line 843 to “although generally associated with large amounts”.

Comment 35: changed “outcropping” to “exposed” line 866, and added “only a” line 884.

Comment 36: changed sentence line 909 to “A reliable Mesozoic K–Ar syn-tectonic crystallization age was obtained only for the”.

Comment 37: changed “may exist in” to “have been reported from” line 934.

Comment 38: corrected minor errors in indicated pages.

Comment 39: comment irrelevant to the present manuscript. No change.

Comment 40: added “Nevertheless, we emphasize that the analytical data presented as ages cannot be treated like high-precision ages from, e.g., modern U–Pb zircon dating, but rather point to a time interval that can, in some cases, be much larger than the analytical error given in the 2-σ error interval” lines 251-254. Also added “Since the mineralogical composition is dominated by smectite and chlorite, the specific peaks for the different illite polytypes are not recognizable due to peak overlap” lines 438-440.
Comment 41: changed location of acronym “TKFZ” to space suggested by Prof. Roberts.

Changes based on comments from Topical Editor Bernhard Grasemann

Comment 1: none (already taken into account in referees’ comments)
Comment 2: none.
Comment 3: added location of analyzed thin sections in legend of Figure 3. Also added “; see Figure 1 for sample location” in legend of Figure 2.

Neoproterozoic and post-Caledonian exhumation and shallow faulting in NW Finnmark from K/–Ar dating and p/T analysis of fault-rocks

Abstract. Well-preserved fault gouge along brittle faults in Paleoproterozoic, volcano-sedimentary rocks of the Raipas GroupSupergroup exposed in the Alta–Kvænangen tectonic window in northern Norway yielded latest Mesoproterozoic (ca. 1050 ± 15 Ma) to mid Neoproterozoic (ca. 825–810 ± 18 Ma) K/–Ar ages. Pressure-temperature estimates from microtextural and mineralogy analyses of fault-rocks indicate that brittle faulting may have initiated at depth of 5–10 km during the opening of the Asgard Sea in the latest Mesoproterozoic–early Neoproterozoic (ca. 1050–945 Ma), and continued with a phase of shallow faulting during to the opening of the Iapetus Ocean–Ægir Sea and the initial breakup of Rodinia in the mid Neoproterozoic (ca. 825–810 Ma). The predominance and preservation of synkinematic smectite and subsidiary illite in cohesive and non-cohesive fault-rocks indicate that Paleoproterozoic basement rocks of the Alta–Kvænangen tectonic window remained at shallow crustal levels (< 3.5 km) and were not reactivated since mid Neoproterozoic times. Slow exhumation rate estimates for the early–mid Neoproterozoic (ca 10–75 m per MaMyr) suggest a period of tectonic quiescence between the opening of the Asgard Sea and the breakup of Rodinia. In the Paleozoic, basement rocks in NW Finnmark were overthrusted by Caledonian nappes along low-angle thrust detachments during the closing of the Iapetus Ocean–Ægir Sea. K/–Ar dating of non-cohesive fault-rocks and microtexture-mineralogy of cohesive fault-rock truncating Caledonian nappe units show that brittle (reverse) faulting potentially initiated along low-angle Caledonian thrusts during the latest stages of the Caledonian Orogeny in the Silurian (ca. 425 Ma) and was accompanied by epidote/chlorite-

rich, stilpnomelane-bearing cataclasite (type 1) indicative of a faulting depth of 10–16 km. Caledonian thrusts were inverted (e.g., Talvik fault) and later truncated by high-angle normal faults (e.g. Langfjord–Vargsund, Langfjorden–Vargsundet fault) during subsequent, late Paleozoic, collapse-related widespread extension in the Late Devonian–early Carboniferous (ca. 375–325 Ma). This faulting period was accompanied by quartz- (type 2), calcite- (type 3) and laumontite-rich cataclasites (type 4), which crosscuttingwhose cross-cutting relationships indicate a progressive exhumation of Caledonian rocks to zeolite-facies conditions (i.e., depth of 2–8 km). An ultimate period of minor faulting occurred in the late Carboniferous–mid Permian (315–265 Ma) and exhumed Caledonian rocks to shallow depth 1–3.5 km. Alternatively, late Carboniferous (?) – early/mid Permian K/Ar ages may reflect late Paleozoic weathering of the margin. Exhumation rates estimates indicate rapid Silurian–early Carboniferous exhumation and slow exhumation in the late Carboniferous–mid Permian, supporting decreasing faulting activity from the mid-Carboniferous. NW Finnmark remained tectonically quiet in the Mesozoic–Cenozoic.

1. Introduction

Onshore and nearshore areas of Finnmark and shallow parts of the Barents shelf, such as the Finnmark Platform, are underlain by Archean–Paleoproterozoic basement rocks exposed onshore in coastal ridges (Zwaan, 1995; Bergh et al., 2010) and tectonic windows (Reitan, 1963; Roberts, 1973; Zwaan &and Gautier, 1980; Gautier et al., 1987; Bergh &and Torske, 1988; Jensen, 1996) of the overlying Caledonian nappe stack (Roberts, 1973; Corfu et al., 2014). These basement rocks are part of the Fennoscandian Shield onto which Caledonian nappes were overthrusted in the Silurian (Townsend, 1987; Corfu et al., 2014; Figure 1Figure 1). Near the end of Caledonian contraction, lateral escape initiated in a NE–SW direction, and this episode of deformation was constrained to ca. 431–428 Ma by U–Pb and Ar–Ar dating (Kirkland et al., 2005, 2006; Corfu et al., 2006). Post-Caledonian extension started in the Devonian (Guise and Roberts, 2002; Roberts et al., 2011; Davids et al., 2013; Koehl et al., 2018) with reactivation of Proterozoic and Caledonian ductile fabrics and continued through the mid Permian and, later on, through the Mesozoic and early Cenozoic when multiple brittle faults onshore and nearshore and major offshore rift basins formed prior to the opening of the NE Atlantic Ocean (Breivik et al., 1995; Gudlaugsson et al., 1998; Bergh et al., 2007; Faleide et al., 2008; Indrevær et al., 2013; Koehl et al., 2018).

Formatted: Font: Not Bold

Formatted: Font: Not Bold, Not Italic

Critical to the understanding of post-Caledonian extension and brittle fault evolution is the nature and timing of faulting. We have dated multiple brittle faults using K–Ar method of non-cohesive fault rocks (Lyons &and Snellenburg, 1971) along several major brittle faults in NW Finnmark, along fault segments of the Trollfjorden–Komagelva Fault Zone (TKFZ; Siedlecka &and Siedlecki, 1967; Siedlecki, 1980; Herrevold et al., 2009; Figure 1Figure 1) and Langfjorden–Vargsundet fault (LVF; Zwaan &and Roberts, 1978; Lippard &and Roberts, 1987; Figure 1Figure 1). The TKFZ, which crops out in northern (Koehl et al. submitted) and eastern Finnmark (Siedlecki, 1980), represents a major Neoproterozoic fault zone that was active through various episodes of (Timanian and Caledonian) transpression and subsequent extension (Siedlecka and Siedlecki, 1967; Roberts, 1972; Siedlecka, 1975; Herrevold et al., 2009), whereas the LVF corresponds to a large, zigzag-shaped, NE–SW trending striking, margin-parallel fault complex, the age of which age is yet uncertain (Zwaan &and Roberts, 1978; Roberts &and Lippard, 2005; Koehl et al., submitted). This fault, however, extends onto the eastern Finnmark Platform east where it bounds a triangular-shaped, half-graben basin of presumed Carboniferous age (Figure 1Figure 1; Koehl et al., 2018).

The main goal of this work is to constrain the timing of brittle fault initiation (Proterozoic and/or post-Caledonian), and to discuss the reactivation and exhumation history of faults in basement rocks and Caledonian units of NW Finnmark,. We focus on margin-parallel brittle faults in basement rocks of the Alta–Kvænangen tectonic window in the Altafjorden area, for comparison with exposed fault segments of the Neoproterozoic, margin-oblique TKFZ (Figure 1Figure 1). We also mapped and analyzed post-Caledonian fault segments and splays of the margin-parallel LVF to compare with the age of similar, offshore, basin-bounding faults (e.g., Troms–Finnmark and Måsøy fault complexes; Figure 1Figure 1) and associated syn-tectonic sedimentary rocks on the Finnmark Platform and in offshore basins, e.g., the Hammerfest and Nordkapp basins (Gabrielsen et al. 1990; Indrevær et al., 2013).

A second goal is to evaluate the amount of exhumation the margin underwent from the Neoproterozoic to the Caledonian Orogeny and from the collapse of the Caledonides to present times. Thus, we sampled cataclastic fault-rocks along multiple brittle faults including brittle faults that crosscutcross-cut Archean–Paleoproterozoic rocks in fresh road cuts in Altafjorden, and faults like the LVF and TKFZ in Caledonian thrust nappe rocks (Figure 1Figure 1). Then, we analyzed characteristic mineral assemblages for each cataclastic fault-rock, i.e., each faulting event

recorded, which we used in conjunction with ~~crosscutting~~cross-cutting relationships between fault-rocks to reconstruct the evolution of p/T conditions (i.e~~.~~., depth) during faulting and, thus, resolve the exhumation history of the margin. We compare our results with those from analog studies in Western Troms (Davids et al., 2013; Indrevær et al., 2014; Davids et al., submitted) and Finnmark (Torgersen et al., 2014), and discuss regional implications for the tectonic evolution of the Troms-–Finnmark margin during post-Caledonian extension.

2. Geological setting

2.1. Precambrian basement rocks and Caledonian nappes

The bedrock geology of NW Finnmark consists of Archean-–Paleoproterozoic metavolcanic and metasedimentary rocks that occur in tectonic windows, e.g~~.~~., the Alta-–Kvænangen (Bøe ~~&~~and Gautier, 1978; Zwaan ~~&~~and Gautier, 1980; Gautier et al., 1987; Bergh ~~&~~and Torske, 1988), Altenes (Jensen, 1996) and Repparfjord-–Komagfjord tectonic windows (Reitan, 1963; Pharaoh et al., 1982, 1983; Torgersen et al., 2015a), overlying Caledonian nappes, e.g~~.~~., Kalak Nappe Complex (~~Ramsey~~Ramsay et al., 1979, 1985; Kirkland et al., 2005) and Magerøy Nappe (Andersen, 1981, 1984), and intruded by igneous rocks of the Seiland Igneous Province (Robins and Gardner, 1975; Elvevold et al., 1994; Pastore et al., 2016) and Honningsvåg Igneous Complex (Robins, 1998; Corfu et al., 2006). U–Pb ages on titanite from northern Troms provide a minimum estimate of ca. 440–420 Ma for retrograde (< 550°C) Caledonian shearing (Gasser et al., 2015). Precambrian basement rocks are variably metamorphosed but generally show greenschist-–facies mineral assemblages in the study area (Bøe ~~&~~and Gautier, 1978; Zwaan ~~&~~and Gautier, 1980; Bergh ~~&~~and Torske, 1988).

The Caledonian Kalak Nappe Complex is thought by some workers to represent a Laurentia-derived unit that was thrusted over Precambrian basement rocks of Baltica during the Caledonian Orogeny (Kirkland et al., 2008). However, others have provided robust evidence for a Baltican origin (Roberts, 2007; Zhang et al., 2016). Metasedimentary rocks of the Kalak Nappe Complex were metamorphosed to ~~amphibolitic~~ amphibolite-facies conditions and are composed of ~~metapsammites~~psammites, schists and paragneisses ~~crosscut~~cross-cut by low-angle thrusts and shear zones (~~Ramsey~~Ramsay et al., 1979~~,~~, 1985). The Kalak Nappe Complex is intruded by mafic

and ultramafic rocks of the Seiland Igneous Province (Robins and Gardner, 1975; Elvevold et al., 1994) that form two deep roots below the island of Seiland and Sørøya (Pastore et al., 2016). The structurally overlying Magerøy Nappe is made of tightly folded, greenschist-facies, metasedimentary rocks that are separated from the Kalak Nappe Complex by a low-angle thrust onshore Magerøya (Andersen, 1981, 1984). This nappe unit was intruded by mafic rocks of the Honningsvåg Igneous Complex during the Caledonian Orogeny (Robins, 1998; Corfu et al., 2006).

2.2. Brittle faulting and previous age dating in North Norway

2.2.1. Brittle faults trends

Precambrian basement rocks and Caledonian nappes in coastal areas of northern Norway are truncated by several major brittle faults and fracture sets, striking NNE–SSW, ENE–WSW and WNW–ESE (Lippard and Roberts, 1987; Bergh et al. 2007; Eig &and Bergh 2011; Indrevær et al. 2013; Koehl et al. submitted) and of presumed post-Caledonian age. The timing of formation of these faults is uncertain and yet unresolved, but most are thought to be post-Caledonian (Davids et al., 2013, submitted), although Precambrian ages cannot be excluded (Torgersen et al., 2014; Koehl et al., submitted). The three fault sets commonly form two major fault systems. On the one hand, NNE–SSW and ENE–WSW striking faults ~~often~~commonly interact to produce zigzag-shaped fault complexes. An example in NW Finnmark is the LVF, which is made up of alternating ENE–WSW- and NNE–SSW ~~trending~~ striking fault segments (Zwaan &and Roberts, 1978; Lippard &and Roberts, 1987; Koehl et al. submitted) and resembles the offshore, basin-bounding, zigzag-shaped Troms–Finnmark Fault Complex in map- view (Figure 1~~Figure 1~~; Indrevær et al. 2013). This resemblance is verified by offshore prolongation of the LVF into shallow Carboniferous half-graben on the eastern Finnmark Platform ~~east~~ (Koehl et al., 2018). On the other hand, WNW–ESE-striking faults are usually observed as swarms of high-frequency, (sub-) parallel fractures. A key example is the TKFZ, a major Neoproterozoic fault zone that extends from the Varanger Peninsula in the east and crops out onshore the island of Magerøya in the west (Figure 1~~Figure 1~~). This fault complex is made up with multiple segments of sub-parallel, WNW–ESE ~~trending~~ striking brittle faults that die out just west of Magerøya (Koehl et al. submitted). Several of these fault segments were intruded by highly magnetic dolerite dykes during an early Carboniferous extensional event (Roberts et al. 1991; Lippard &and Prestvik 1997; Nasuti et al.

Formatted: Font: Not Bold

Formatted: Font: Not Bold, Not Italic

Formatted: Font: Not Bold

Formatted: Font: Not Bold, Not Italic

2015), when the TKFZ acted as a strike-slip transfer fault and segmented onshore-–nearshore areas of NW Finnmark from the offshore eastern Finnmark Platform-east during late/post-Caledonian extension (Koehl et al., 2018, submitted).

2.2.2. Dating of brittle faults in North Norway

Previous K-–Ar dating of synkinematic illite/muscovite in fault gouge in NW Finnmark showshows that brittle faults in the Repparfjord-–Komagfjord tectonic window, like the Kvenklubben fault, formed in Precambrian times and were reactivated as Caledonian thrustthrusts and, later on, as normal faults during late/post-orogenic extension and subsequent rifting (Torgersen et al. 2014). Non-cohesive fault-rocks sampled by Torgersen et al. (2014) showed enrichment in authigenic smectite and chlorite clay minerals and a rather low content of illite/muscovite.

Farther southwest along the margin, in Western Troms, similar coastal brittle faults display cohesive cataclastic fault-rocks with epidote, chlorite and pumpellyite (Indrevær et al. 2014), and these faults are juxtaposed withagainst amphibolite-facies Precambrian rocks of the West Troms Basement Complex (Zwaan 1995; Bergh et al. 2010). These faults are interpreted to have formed during late Paleozoic extension at depth > 10 km and to have been exhumed to shallower crustal level < 8.5 km, as shown by the widespread occurrence of pumpellyite mineral in fault-rocks. These faults yielded late Paleozoic K/–Ar ages and are possibly associated with post-Caledonian extension in the Devonian-–Carboniferous (Davids et al. 2013).

3. Methods

3.1. Structural field data

In summer 2015, we acquired extensive structural field data along brittle faults in NW Finnmark, which we compiled, interpreted and discussed in earlier contributions (Bergø, 2016; Lea, 2016; Koehl et al., submitted). Among the numerous brittle faults cropping out in NW Finnmark, we selected ten based on their proximity to major faults (e.g.-., LVF, TKFZ), location relative to major faults (footwall/hanging- wall) and according to their strike (parallel to dominant fault trends in Finnmark), which we briefly describe from a structural perspective at outcrop scale.

Fault geometries and kinematic indicators will be used in conjunction with cohesive and non-cohesive fault-rock ~~composition~~compositions and with the ~~result~~results of K~~/~~–Ar dating of fault gouge to propose an evolutionary model for the tectonic evolution and exhumation history of the SW Barents Sea margin and NW Finnmark.

3.2. Microscopic analysis of onshore cohesive fault-rock

We collected cohesive fault-rock samples along numerous brittle faults that we encountered in NW Finnmark (including the ten dated faults), and we used them to investigate kinematic indicators along the selected brittle faults at microscale. We also studied mineral assemblages included in brittle fault-rocks in order to constrain metamorphic facies (p/T) conditions during faulting, therefore adding to the understanding of the exhumation and uplift history of the SW Barents Sea margin. When needed, thin sections were analyzed through an optical microscope and a Scanning Electron Microscope (SEM) at the University of Tromsø to obtain more detailed information about mineral composition.

3.3. K~~/~~–Ar dating and mineralogical analysis of fault gouge

We sampled non-cohesive fault-rock along brittle faults in NW Finnmark and attempted to date authigenic (i.e~~.~~., synkinematic) illite clay mineral formed during faulting events (e.g~~.~~., Vrolijk ~~&~~and van der Pluijm, 1999; Davids et al., 2013; Torgersen et al., 2014; Ksienzyk et al., 2016), ~~which~~whose platy crystal shape differs from their irregular detrital counter-part (e.g~~.~~., Davids et al., 2013; Torgersen et al., 2014). The ten dated samples of non-cohesive fault-rock are referred to as sample 1~~–~~10 in the text and figures. K~~/~~–Ar dating of fault gouge was carried out in the K~~/~~–Ar laboratory facility at the University of Göttingen, Germany. Three grainsize fractions were analyzed for each sample: "2~~–~~6 µm", "< 2 µm" and "< 0.2 µm". Clay-rich fault gouge samples were resolved in water and wet-sieved using a 63 µm sieve. The fraction < ~~63µm~~63 µm was used to extract the clay fractions < ~~2µm~~2 µm by settling in Atterberg cylinders. The fractions < 0.~~2µm~~2 µm have been separated using an ultra-centrifuge. All these fine fractions were examined (XRD) for mineralogical composition and determination of the illite crystallinity using a PHILIPS PW 1800 diffractometer.

Illite crystallinity, the peak width at half height of the 10-Å peak, was determined using a computer program developed at the University of Göttingen. Digital measurement of illite crystallinity was carried out by step scan (301 points, 7-–10° 2Θ, scan step 0.010° 2Θ, integration time 4 s, receiving slit 0.1mm, automatic divergence slit). Illite crystallinity determinations have been shown to be a sensitive indicator for the degree of very low-–grade metamorphism in clastic ~~sediments~~sedimentary rocks. Reviews of the preparation techniques and the interpretation have been given for example by Kisch (1991) and Krumm (1992). All samples have been investigated in duplicates (A and B). The measurements were carried out in the „air dry“ and the „ethylene glycol saturated“ status in order to detect expandable layers of smectite type minerals. Smectite classification (Reichweite) has been determined following Moore ~~&~~and Reynolds (1997). Illite crystallinity is expressed as Kübler Index in (KI, Δ°2Θ), the limits for diagenesis/anchizone (ca. 200°C) and anchizone/epizone (300°C) are 0.420° and 0.250° Δ°2Θ (Kübler 1967, 1968, 1984), respectively.

The argon isotopic composition was measured in a pyrex glass extraction and purification line coupled to a Thermo Scientific ARGUS VI ™ noble gas mass spectrometer operating in static mode. The amount of radiogenic ^{40}Ar was determined by isotope dilution method using a highly enriched ^{38}Ar spike from Schumacher, Bern (Schumacher, 1975). The spike is calibrated against the biotite standard HD-B1 (Fuhrmann et al., 1987). The age calculations are based on the constants recommended by the IUGS quoted in Steiger ~~&~~and Jäger (1977). Potassium was determined in duplicate by flame photometry using a BWB-XP flame photometer ™. The samples were dissolved in a mixture of HF and HNO_3 according to the technique of Heinrichs ~~&~~and Herrmann (1990). The analytical error for the K/-–Ar age calculations is given on a 95% confidence level (2σ). Details of argon and potassium analyses for the laboratory in Göttingen are given in Wemmer (1991).

Temperature constraints from illite-–smectite clay minerals

Since the dominant synkinematic clay mineral in the analyzed fault-rocks are smectite and subsidiary interlayered illite-–smectite clay, we use the smectite-–illite clay mineral reaction to infer maximum/minimum temperature estimates for faulting events in NW Finnmark (Eberl et al. 1993; Huang et al. 1993; Morley et al. 2018). Synkinematic illite ~~often~~commonly grows due to illitisation of smectite and, alternatively, due to dissolution-–precipitation of existing clay minerals of the bedrock (Vrolijk ~~&~~and van der Pluijm, 1999). Illitisation along fault surfaces is enhanced by

temperature increase, e.g.~~.~~., related to frictional heating, hydrothermal processes or burial, grain comminution, strain, changes in fluid composition and fluid~~/~~-rock ~~ration~~ratio (Vrolijk ~~&~~and van der Pluijm, 1999). Illitisation of smectite is commonly thought to begin at a temperature range of 40~~–~~–70°C (Jennings ~~&~~and Thompson, 1986; Harvey ~~&~~and Browne, 2000; Ksienzyk et al., 2016).

Interpretation of inclined age spectra

K~~/~~–Ar dating requires targeted minerals to behave as "closed systems" with no loss of argon or potassium (Lyons ~~&~~and Snellenburg, 1971). Mineral closure temperature varies with grainsize and is lower for finer grains. For example, aggregates of fine grains may accidentally be incorporated and dated as part of coarser fractions of fault gouge, thus ~~leading~~causing coarse fractions to yield younger ages than finer fractions (Hamilton et al., 1989; Heizler ~~&~~and Harrison, 1991). More specifically along shallow faults, illite grains < 2 µm crystallize below the closure temperature of the K~~–~~–Ar system (> 250°C; Velde, 1965) and, thus, ~~provide with~~yield robust, synkinematic crystallization ages rather than less accurate, generally younger cooling ages obtained along deeper faults (Hunziker et al., 1986; Ksienzyk et al., 2016). Further, ~~contrarily~~contrary to metamorphism-related heating, the short heating time associated with hydrothermal events or frictional heating along brittle faults ~~are~~is unlikely to reset illite ages, which would require longer exposure to ~~temperature~~temperatures > 250°C (Torgersen et al., 2014), thus suggesting that K~~/~~–Ar ages on illite along shallow faults provide reasonable estimates of the age of faulting. Nevertheless, we emphasize that the analytical data presented as ages cannot be treated like high-precision ages from, e.g., modern U–Pb zircon dating, but rather point to a time interval that can, in some cases, be much larger than the analytical error given in the 2-σ error interval.

Formatted: English (United Kingdom)

Mixing of host-rock inherited minerals, e.g.~~.~~., detrital illite~~–~~–muscovite, with authigenic illite may influence K~~/~~–Ar ages and cause age dispersion in faults, notably in the coarser fractions dated (Hower et al., 1963; Vrolijk ~~&~~and van der Pluijm, 1999). However, inherited illite~~–~~–muscovite may be distinguished from authigenic clay minerals as they display more irregular shapes than their generally platy authigenic ~~counter-parts~~counterparts (e.g.~~.~~., Torgersen et al., 2014). In addition, faulting may even isotopically reset fine-grained, ~~hostrock~~host-rock illite~~–~~–muscovite, thus yielding ages bearing no influence of inherited, older minerals (Vrolijk ~~&~~and van der Pluijm, 1999). In addition, fault-inherited illite may also affect K~~/~~–Ar ages, which is especially verified along repeatedly active, progressively exhumed faults because high-temperature illite may

survive low-temperature reactivation of the faults (Davids et al., 2013; Viola et al., 2013). Another mineral that may have a significant impact on K/–Ar ages is host rock-inherited K-feldspar. Most importantly, K-feldspar has a significantly lower closure temperature (350–150°C) than illite clay mineral (> 250°C), hence yielding younger ages than the actual age of faulting, particularly for finer fractions in fault gouges (Lovera et al., 1989). Hornblende may also affect K/–Ar dating of illite (Torgersen et al., 20152015b) but was not encountered in any fault-rock samples in NW Finnmark and its effect are therefore not considered here.

4. Results

We sampled brittle fault rocks for K–Ar dating and microtextural analysis from several dominant fault systems and fault trends in NW Finnmark (Figure 1Figure 1; Koehl et al., submitted). The sampling sites include (i) faults in Paleoproterozoic rocks of the Raipas GroupSupergroup (Zwaan &and Gautier, 1980) in Altafjorden (samples 3 &and 4), (ii) faults in the Caledonian Kalak Nappe Complex along segments and splay-faults of the LVF (samples 1, 2, 5, 6 &and 7), and (iii) faults in rocks of the Kalak Nappe Complex and Magerøy Nappe (sample 8, 9 &and 10) adjacent to segments of the TKFZ (Figure 1Figure 1). For the sampled faults, we first describe trends, field relations and kinematics of the faults. Second, we describe the mineral assemblages and microstructures of sampled cohesive fault-rocks in order to infer deformation mechanisms and estimate the p-/T conditions during faulting and exhumation. Third, we present the K–Ar data and mineralogical results obtained on fault gouge.

4.1. Field relations of sampled brittle faults in NW Finnmark

4.1.1. Brittle faults in Paleoproterozoic basement rocks (samples 3 &and 4)

Samples 3 and 4 (Figure 2Figure 2a &and b) are from the Altafjorden fault 1 and 2, NW-dipping brittle faults in new, fresh road-cuts along the western shore of Altafjorden, truncating meta-arkoses of the Paleoproterozoic Raipas GroupSupergroup (Skoadduvarri Sandstone) of the Alta–Kvænangen tectonic window (Zwaan &and Gautier, 1980; Bergh &and Torske, 1986, 1988). The two sampled faults are located a few tens of meters away from each other, display m-thick fault-cores mostly composed of grey-colored clay particles in non-cohesive fault gouge and partly

Formatted: Font: Not Bold, Not Italic

cohesive cataclasites (Figure 2~~Figure 2~~a ~~&~~and b). The Altafjorden fault core also show multiple slip surfaces cemented by cm-thick quartz grains (Figure 2~~Figure 2~~a). Slickenside lineations on fault surfaces indicate normal dip-slip movement. A mafic band is bent into (drag folded) the fault core facilitating normal down-~~to the~~-NW sense of shear (Figure 2~~Figure 2~~a). The absence of this mafic bed in the footwall of the Altafjorden fault suggests that the fault accommodated vertical displacement > 5~~–~~–6 m.

4.1.2. Brittle faults along the ~~LVF~~Langfjorden–Vargsundet fault (samples 1, 2, 5, 6 ~~&~~and 7)

We sampled fault-rocks along several segments/splay-faults of the LVF (Torgersen et al., 2014; Koehl et al., submitted). This regional fault complex can be traced from Sørkjosen in the south (~~cf.~~ location of samples 1 ~~&~~and 2 in Figure 1~~Figure 1~~) to the Porsanger Peninsula in the north (Figure 1~~Figure 1~~) and defines a zigzag-shaped pattern of alternating, NNE~~–~~–SSW to ENE~~–~~–WSW trending fault segments that dominantly dip WNW and NNW, respectively (Koehl et al., submitted). Samples 1 and 2 are taken from two minor NW-dipping fault splays (Figure 2~~Figure 2~~c ~~&~~and d) in the footwall of the Sørkjosen fault, a major fault-segment of the LVF (Figure 1~~Figure 1~~; Koehl et al., submitted). The faults ~~crosscut~~cross-cut granodioritic gneisses of the Kalak Nappe Complex and display thin, 10~~–~~–40 cm-thick fault-cores with lenses of dark clayish gouge material (Figure 2~~Figure 2~~c ~~&~~and d). The northern ~~of these faults~~fault accommodates ca. 5~~–~~–8 m top-~~to the~~-NW, normal displacement of a 20~~–~~–30 cm-thick layer of mafic amphibolite (Figure 2~~Figure 2~~c), while the southern fault offsets the same mafic layer by ca. 2 m top-~~to the~~-NW (Figure 2~~Figure 2~~d). Slickenside lineations along these two faults support normal dip-slip sense of shear (Figure 2~~Figure 2~~c ~~&~~and d).

Along strike ~~northeastward~~to the northeast, we sampled another subsidiary fault linked to the LVF along the western shore of Altafjorden, the Talvik fault (sample 5; Figure 1~~Figure 1~~), a low-angle, ~~N~~north-dipping fault that ~~crosscuts~~cross-cuts arkosic ~~meta~~-psammites of the Kalak Nappe Complex (Figure 2~~Figure 2~~e). The Talvik fault shows evidence of both brittle and ductile faulting in a ca. one meter-thick fault-core ~~made~~composed of semi-ductile, mylonitic fault-rock, overprinted by calcite- and quartz-bearing cataclasite, as well as thin layers of non-cohesive fault gouge along distinct fault surfaces (Figure 2~~Figure 2~~e). Field observations of quartz~~-~~ sigma clasts and S-C fabrics in the mylonites reveal top-~~to the~~-south thrusting, whereas slickengrooves and asperities are present along distinct brittle fault surfaces, implying top-~~to the N~~north motion along

the Talvik fault (Figure 2~~Figure 2~~e). Brittle offset of ductile quartz sigma-clasts confirms that brittle fabrics are younger than ductile fabrics.

Sample 6 was taken along a high-angle~~, NNE-SSW trending and~~ WNW-dipping brittle fault that crops out along the eastern shore of Altafjorden ~~(cf. (~~Figure 1~~Figure 1~~ and Figure 2~~Figure 2~~f). This fault defines the southeastern boundary of a graben structure in garnet-rich ~~meta-~~psammite of the Kalak Nappe Complex and is characterized by a ca. one meter-thick fault-core made of non-cohesive clayish fault gouge and adjacent epidote-rich cataclasite (Figure 2~~Figure 2~~f). Slickenside lineations indicate down-~~to the-~~WNW, dip-slip normal movement, which is consistent with normal dip-slip offsets of boudinaged mafic dykes across nearby NNE-~~-~~SSW trending faults (Figure 2~~Figure 2~~f).

The final fault-rock sample along LVF segments and splays (sample 7; Figure 1~~Figure 1~~) is from the steep~~, NNE-SSW trending,~~ SE-dipping Snøfjorden-~~-~~Slatten fault on the Porsanger Peninsula ~~(cf. (~~Figure 1~~Figure 1~~ and Figure 2~~Figure 2~~g; Passe, 1978; Townsend, 1987b), which represents a major, antithetic fault segment/splay of the LVF (Koehl et al., submitted). This fault ~~crosscuts~~cross-cuts felsic metasedimentary rocks and micaschists of the Kalak Nappe Complex and displays a several meter-wide fault-core that is made of non-cohesive iron- and quartz-rich fault gouge, including a few lenses of cohesive fault-rock (Figure 2~~Figure 2~~g). Slickensided fault surfaces reveal down-~~to the-~~SE, normal dip-slip movement, probably a few meters to a few tens of meters due to the presence of the same host rock on both sides of the fault (Figure 2~~Figure 2~~g).

4.1.3. Brittle faults adjacent to the ~~TKFZ~~Trollfjorden–Komagelva Fault Zone (samples 8, 9 ~~&~~and 10)

Subvertical, WNW-~~-~~ESE~~-trending-~~striking brittle faults and fracture systems are widespread ~~near and-~~within units of the Magerøy Nappe ~~units-~~on the Porsanger Peninsula and on the island of Magerøya (Figure 1~~Figure 1~~; ~~cf.~~ Koehl et al. submitted). Sample 8 is from fault gouge found along an anomalously low-angle~~, WNW-ESE striking,~~ NNE-dipping fault on the Porsanger Peninsula (Figure 1~~Figure 1~~ and Figure 2~~Figure 2~~h). The fault ~~crosscuts~~cross-cuts garnet-mica gneisses of the Kalak Nappe Complex, adjacent to a lens of preserved Magerøya Nappe ~~unit~~rocks on the Porsanger Peninsula (Kirkland et al., 2007). This fault comprises thin, dm-scale lenses of dark clay particles along the fault-core and damage zone with splaying fault geometries (Figure 2~~Figure 2~~h). Oblique normal-sinistral movement is inferred from slickenside lineations (Figure

2Figure 2h), and the amount of displacement probably does not exceed a few tens of meters because garnet-bearing gneisses occur on both sides of the fault.

Farther north, on Magerøya, sample 9 corresponds to a steep, WNW-–ESE- to E-–W trending, S-striking, south-dipping fault (Figure 1Figure 1 and Figure 2Figure 2i) in a new quarry within a suite of weakly foliated gabbroic rocks of the Honningsvåg Igneous Complex (Robins, 1998; Corfu et al., 2006). The sampled fault-core includes two thin, 5-–10 cm-thick layers of light-colored, non-cohesive clay particles (Figure 2Figure 2i).

The last fault we sampled for K/–Ar dating (sample 10) was taken along a steep, WNW-ESE striking, NNE-dipping brittle fault in the western part of Magerøya (cf. (Figure 1Figure 1 and Figure 2Figure 2j). This fault is part of a high-frequency, WNW-–ESE trending-striking lineament and brittle fault system that corresponds to fault segments of the TKFZ, which pervasively truncate metasedimentary rocks of the Kalak Nappe Complex in western Magerøya (Koehl et al., submitted) and displays a ca. 0.5 m-thick fault-core made up with light-colored clay particles (Figure 2Figure 2j).

4.2. Mineralogy and microtextural analysis of cohesive fault-rock

4.2.1. Cohesive fault-rocks within the Alta-–Kvænangen tectonic window

In order to describe and analyze cohesive brittle fault-rock characters and mineralogical and textural changes during cataclasis, the host rock characters are used as frame. Cohesive fault-rock was found along most exposed brittle faults crosscuttingcross-cutting Precambrian volcano-sedimentary rocks of the Alta-–Kvænangen tectonic window (Figure 2Figure 2a &and b). The host rocks are fairly undeformed but underwent low-grade (greenschist-facies) metamorphic conditions during the Svecofennian Orogeny , and developed a weak, bed-parallel foliation (Bøe &and Gautier, 1978; Zwaan &and Gautier, 1980; Bergh &and Torske, 1988). This foliation comprises partly recrystallized, sigma-shaped grains of quartz and feldspar locally incorporated into an S-C foliation made of elongated crystals of white mica (Figure 3Figure 3a).

Brittle faults analyzed in the present study crosscutcross-cut both meta-sandstones and metamorphosed carbonate-rich host-rocks, and include three types of cataclasites and mineral precipitations. The first type shows a matrix of finely crushed clasts of quartz (Figure 3Figure 3b). The second type is made of a partly healed, calcite-cemented cataclasite, which crystals display

both type II and IV twinning (~~Lerman 1999~~Ferrill, 1991; Burkhard, 1993; Figure 3~~Figure 3~~c). The third type includes cataclasite with abundant brownish to reddish matrix of very fine-grained clay- (smectite and subsidiary illite) and iron-rich minerals associated with iron-bearing precipitations, ~~often~~commonly truncating veins of recrystallized quartz and quartz-rich cataclasite (Figure 3~~Figure 3~~b). Iron-bearing precipitations ~~often~~ appear to localize along fractures developed parallel to ~~pre-existing~~preexisting, white-mica, S-C-C' foliation (Figure 3~~Figure 3~~b). Relative timing of quartz-, calcite- and clay-rich cataclasite could not be directly resolved from ~~crosscutting~~cross-cutting relationships.

4.2.2. Cohesive fault-rocks within Caledonian nappes

Metamorphic Caledonian host rocks consist of a variety of granodioritic gneisses, metasandstones, metapelites, amphibolites/~~metavolcanics~~metavolcanites, gabbros and ~~micaschists~~mica schists. When truncated by brittle faults, most rocks are altered and/or display retrograde mineral assemblages. Notably, in mafic/granodioritic host rocks, biotite is systematically retrograded into chlorite in the vicinity of brittle faults (Figure 3~~Figure 3~~d), host rocks are generally enriched in epidote at the expense of amphibole, and garnet porphyroblasts are highly fractured (Figure 3~~Figure 3~~e). Brittle faults ~~crosscutting~~cross-cutting Caledonian rocks comprise up to 1~~-~~–2 m wide lenses of fractured host rocks showing preserved ductile fabrics, such as widespread muscovite~~-~~–biotite and S-C-C' foliation with feldspar sigma-clasts partly recrystallized into quartz (e.g~~.~~.., along the Sørkjosen and Snøfjorden~~-~~–Slatten faults; Figure 3~~Figure 3~~d ~~&~~and f). Typically, S, C and C' foliation surfaces are partly replaced by cataclastic fault-rocks and, thus, may have localized subsequent brittle faulting (Figure 3~~Figure 3~~g), as observed along the brittle~~-~~–ductile Talvik fault (Figure 2~~Figure 2~~e).

We identified five texturally different types of cataclasites ~~crosscutting~~cross-cutting each other in a systematic order. The first type of cataclasite (type 1) is ~~made~~composed of fine-grained, rounded to sub-rounded clasts of epidote and chlorite (Figure 3~~Figure 3~~e ~~&~~and h), ~~often~~commonly reworked into large, angular clasts incorporated into subsequent cement or cataclastic matrix (Figure 3~~Figure 3~~e ~~&~~and i). Epidote~~-~~–chlorite fracture precipitations sometimes appear undeformed (Figure 3~~Figure 3~~j). ~~Occasionally~~In places, epidote~~-~~–chlorite~~-~~bearing veins comprise rounded clasts of a brownish mineral showing moderate to strong relief (Figure 3~~Figure 3~~h). EDS

analysis reveals that this mineral is enriched in calcium, iron, silica, aluminium, magnesium and oxygen (Figure 3~~Figure 3~~k), and, thus, may correspond to stilpnomelane (Eggleton, 1972).

The second type of cataclasite (type 2) is composed of very fine-grained, rounded to sub-rounded clasts of quartz (Figure 3~~Figure 3~~h). This type of cataclasite is ~~often~~commonly observed adjacent to host rock clasts (Figure 3~~Figure 3~~e), regularly incorporates angular clasts of epidote-rich cataclasite (Figure 3~~Figure 3~~e ~~&~~and h), and occurs in conjunction with veins of recrystallized quartz (Figure 3~~Figure 3~~h).

The third type of cataclasite (type 3) is widespread along fault segments and splay-faults of the LVF (e.g.~~.~~., Sørkjosen, Straumfjordbotn, Langfjorden, Øksfjorden, Altafjorden 1 ~~&~~and 2, and Talvik faults) and is characterized by poorly sorted, angular clasts of calcite (Figure 3~~Figure 3~~l) ~~often~~generally associated with abundant, locally undeformed, calcite cement, showing type I and type II twinning (Figure 3~~Figure 3~~i; ~~Lerman 1999).~~Ferrill, 1991; Burkhard, 1993). Calcite crystals consistently ~~crosscut~~cross-cut veins of recrystallized quartz, and epidote- and quartz-rich cataclasites (Figure 3~~Figure 3~~e).

The fourth type of cataclasite (type 4) consists of abundant, new-grown, mildly cataclased, prismatic/columnar mineral grains with acute edges and steep-oblique terminations showing low relief, low refraction index and three sets of cleavage (Figure 3~~Figure 3~~e ~~&~~and m). We interpret this mineral as laumontite, i.e~~.~~., a high-temperature zeolite mineral (Dill et al., 2007; Triana et al., 2012). In the study area, laumontite crystals commonly grew with their long-crystallographic axis perpendicular to brittle fractures (Figure 3~~Figure 3~~m) and consistently ~~crosscut~~cross-cut epidote- and quartz-rich cataclasites and epidote~~-~~-chlorite- and calcite-filled veins ~~(cf.~~ (Figure 3~~Figure 3~~e).

The fifth type of cataclasite (type 5) shows enrichment in very fine-grained, iron-oxide bearing mineral precipitations and an even more fine-grained, microscopic matrix of brownish and greyish clay minerals (Figure 3~~Figure 3~~e, h, l ~~&~~and n). These ~~cataclastes~~cataclasites truncate and ~~often~~commonly incorporate clasts of epidote~~-~~-chlorite~~,~~., quartz- and calcite-rich cataclasite and associated mineral veins ~~(cf.~~ (Figure 3~~Figure 3~~e, l ~~&~~and n).

4.3. Fault gouge mineralogy and K~~/~~-Ar ages

XRF analyses of various grainsize fractions of the sampled fault gouges in NW Finnmark consistently show (1) high smectite content ~~often~~commonly associated with chlorite (mixed-layer chlorite-~~–~~smectite), e.g.~~.~~., samples 1, 2, 6 ~~&~~and 8 (Figure 1~~Figure 1~~), (2) a relatively low content in illite and (3) variable amount of residual quartz (Table 1~~Table 1 &~~and Appendix A). The only exception is sample 8 from the Porsanger Peninsula ~~(cf.~~ (Figure 2~~Figure 2~~h), which contains higher amounts of illite and quartz together with smectite, chlorite and kaolinite clay minerals (Table 1~~Table 1 & Appendix A).~~and Appendix A). Since the mineralogical composition is dominated by smectite and chlorite, the specific peaks for the different illite polytypes are not recognizable due to peak overlap. The analysis of the diffraction spectrum for all three grainsize fractions indicates that fault gouge from western Magerøya (sample 10) is ~~made~~composed of almost pure smectite (Figure 2~~Figure 2~~j, Table 1~~Table 1~~ and Appendix A). Traces of K-feldspar, indicated by minor peaks at 27.3~~–~~27.4 on inclined spectra (Table 1~~Table 1 &~~and Appendix A), were observed in all three grainsize fractions of fault gouge samples 1 ~~&~~and 2 in Sørkjosen (Figure 1~~Figure 1~~, Figure 2~~Figure 2~~c ~~&~~and d, Table 1~~Table 1 &~~and Appendix A), in the coarse (2~~–~~6 µm) fraction of sample 6 from the eastern shore of Altafjorden (Figure 1~~Figure 1~~, Figure 2~~Figure 2~~f, Table 1~~Table 1 &~~and Appendix A), in the coarse and intermediate fractions of sample 7 from the Snøfjorden~~–~~Slatten fault on the Porsanger Peninsula (Figure 1~~Figure 1~~, Figure 2~~Figure 2~~g, Table 1~~Table 1 &~~and Appendix A), and in sample 10 along a WNW~~–~~ESE~~-trending~~-striking fault in western Magerøya (Figure 1~~Figure 1~~, Figure 2~~Figure 2~~j, Table 1~~Table 1 &~~and Appendix A). Sample 9 from the Honningsvåg Igneous Complex on Magerøya (Figure 2~~Figure 2~~i) shows very low potassium content ~~(cf.~~ (Table 2~~Table 2~~), which resulted in high 2σ errors associated with the K~~/~~–Ar ages obtained for all three fractions ~~(cf.~~ (Table 2~~Table 2~~). We also noticed the presence of possible laumontite and/or stilbite in this sample (Table 1~~Table 1 &~~and Appendix A; Triana et al., 2012).

4.3.2. K~~/~~–Ar dating results

Precambrian ages

All three dated fractions of sample 3 and 4 (Figure 1~~Figure 1 &~~, and Figure 2~~Figure 2~~a ~~&~~and b) yielded Precambrian ages (Table 2~~Table 2~~, Figure 4~~Figure 4 &~~and Figure 5~~Figure 5~~). For sample 3, the coarse fraction yielded a late Mesoproterozoic age (1050.7 ± 12.2 Ma; ~~cf.~~ Figure 4~~Figure 4 &~~and Figure 5~~Figure 5~~). The intermediate and finest fractions of this sample both yielded

early Cryogenian (Neoproterozoic) ages, 806.4 ± 10.7 and 824.7 ± 12.7 Ma respectively (Table 2~~Table 2 &~~, and Figure 4~~Figure 4~~ ~~&~~and Figure 5~~Figure 5~~). The intermediate fraction yielded a slightly younger age ~~in tendency~~ compared ~~to~~with the finest fraction, taking the errors into account, both ages do not differ significantly~~.~~, and we interpret them both as syn-kinematic crystallization along an active normal fault. Nevertheless, these K~~/~~–Ar ages from well-preserved, non-cohesive fault gouges suggest that the Altafjorden fault 1 (Figure 2~~Figure 2~~a) formed in late Mesoproterozoic times and was reactivated at least once in the Neoproterozoic (early Cryogenian). Younger, post-Caledonian reactivation seems unlikely, as the sensitivity of the K~~/~~–Ar geochronometer would certainly have recorded subsequent reactivation by yielding younger ages.

Similar Precambrian K~~-~~–Ar ages were obtained for the three fractions of sample 4 from the Altafjorden fault 2 (Figure 1~~Figure 1~~, Figure 2~~Figure 2~~b, Figure 4~~Figure 4~~ ~~&~~and Figure 5~~Figure 5~~). Here, the coarse-grained fraction yielded a late Mesoproterozoic age of 1054.2 ± 14.7 Ma, the intermediate fraction a Tonian (early Neoproterozoic) age of 943.8 ± 17.3 Ma, and the finest fraction a Cryogenian (mid Neoproterozoic) age of 811.3 ± 17.8 Ma (Table 2~~Table 2~~, Figure 4~~Figure 4~~ ~~&~~and Figure 5~~Figure 5~~). Considering the proximity of the Altafjorden faults 1 and 2 (samples 3 ~~&~~and 4; Figure 1~~Figure 1~~) and the comparable ages obtained for these faults, we consider the K~~/~~–Ar ages to be reliable and likely reflecting syn-kinematic crystallization of authigenic illite during protracted Mesoproterozoic~~-~~–Neoproterozoic tectonic events. These results further suggest that the Altafjorden faults 1 and 2 were not reactivated in the Phanerozoic, as further reactivation would necessarily have been recorded and resulted in younger ages.

Late Paleozoic ages

Most ~~of the~~ dated fault gouges from segments of the LVF and TKFZ in the Kalak Nappe Complex~~, as well as those along the TKFZ~~ and Magerøy Nappe on the Porsanger Peninsula and Magerøya yielded late Paleozoic ages (Table 2~~Table 2~~, Figure 4~~Figure 4~~ ~~&~~and Figure 6~~Figure 6~~). The coarse fraction of the Talvik fault (sample 5; Figure 1~~Figure 1~~ ~~&~~and Figure 2~~Figure 2~~e) yielded a Silurian age of 427.3 ± 8.4 Ma, the intermediate fraction a Tournaisian (early Carboniferous) age of 353.7 ± 4.1 Ma and the finest fraction an early Permian age of 282.1 ± 6.3 Ma (Figure 4~~Figure 4~~ ~~&~~and Figure 6~~Figure 6~~). These ages are interpreted as syn-tectonic crystallization ages and may indicate brittle faulting at the end of the Caledonian Orogeny and reactivation during post-Caledonian extension in the early Carboniferous~~-~~–mid Permian~~,~~ (see discussion).

The intermediate and fine-grained fractions of sample 6 along the eastern shore of Altafjorden (Figure 1~~Figure 1~~ ~~&~~and Figure 2~~Figure 2~~f) yielded earliest Permian and latest Carboniferous syn-kinematic crystallization ages respectively (292.6 ± 4.0 Ma; 298.5 ± 5.0 Ma), while the coarse-grained fraction yielded a Jurassic age of 208.5 ± 3.1 Ma (Table 2~~Table 2~~, Figure 4~~Figure 4~~ ~~&~~and Figure 6~~Figure 6~~). A possible explanation for this discrepancy is that the coarse fraction of sample 6 partly consists of aggregates of smaller grains reflecting a much younger faulting event (Hamilton et al., 1989; Heizler ~~&~~and Harrison, 1991). However, XRF analysis of the sample suggests that the anomalous, younger age obtained for the coarse fraction may be the product of excess potassium due to the presence of K-feldspar in the sample ~~(cf.~~ (Table 1~~Table 1~~ ~~&~~and Appendix A; Lovera et al., 1989).

The sample taken along the low-angle, WNW~~-~~–ESE~~-trending~~-striking fault on the Porsanger Peninsula (sample 8; Figure 1~~Figure 1~~ ~~&~~and Figure 2~~Figure 2~~h) yielded similar latest Carboniferous~~-~~–earliest Permian ages all included within a 5 Ma time span of 302.3 ± 6.5 Ma, 297.6 ± 7.7 Ma and 296.6 ± 3.8 Ma ~~(cf.~~ (Table 2~~Table 2~~, Figure 4~~Figure 4~~ ~~&~~and Figure 6~~Figure 6~~). ~~This suggests~~These syn-kinematic crystallization ages suggest that the fault was not reactivated after the earliest Permian, as the finest fraction would have recorded a younger faulting event and, thus, yielded a younger age. It is, however, possible that the fault accommodated earlier faulting events.

Fault gouge sampled along a WNW~~-~~–ESE~~-trending~~-striking fault segment of the TKFZ (Koehl et al., submitted) near Gjesvær in western Magerøya (sample 10; Figure 1~~Figure 1~~ ~~&~~and Figure 2~~Figure 2~~j) yielded late Carboniferous (312.5 ± 8.7 Ma), early Permian (284.0 ± 6.2 Ma) and mid Permian (270.8 ± 6.0 Ma) ages, respectively, for the coarse, intermediate and finest fractions, ~~suggesting~~which we all interpret as syn-tectonic crystallization ages. These ages suggest that the fault experienced multiple extensional faulting events from the late Carboniferous to mid-Permian (Table 2~~Table 2~~, Figure 4~~Figure 4~~ ~~&~~and Figure 6~~Figure 6~~).

Fault gouge sample 9 from an E~~-~~–W- to WNW~~-~~–ESE~~-trending~~-striking fault within the Honningsvåg Igneous Complex in the Magerøy Nappe (Figure 1~~Figure 1~~ ~~&~~and Figure 2~~Figure 2~~i), contains very low amounts of potassium (Table 2~~Table 2~~). This, together with a high contamination of atmospheric argon, resulted in high errors for all three dated fractions. Considering the high 2σ error percentage associated ~~to~~with the K~~/~~–Ar ages obtained for this sample, the coarse fraction may cover a time span of faulting from the mid-Carboniferous (early Serpukhovian) to the Late

Pennsylvanian (Gzhelian), 315.6 ± 13.6 Ma (Table 2~~Table 2~~, Figure 4~~Figure 4~~ &~~&~~and Figure 6~~Figure 6~~). The finest fraction exhibits an even higher 2σ error percentage, and the age window included within 2σ interval spans from the early Permian to the Middle Triassic (Table 2~~Table 2~~, Figure 4~~Figure 4~~ &~~&~~and Figure 6~~Figure 6~~). The intermediate fraction yielded a younger age (234.7 ± 18.0 Ma) than the finest fraction (265.2 ± 23.6 Ma), which is considered to be erroneous. The ages obtained for the coarse and fine fractions are interpreted to represent syn-kinematic crystallization of authigenic illite. Brittle faulting along this fault most likely initiated in the mid-Carboniferous and the fault was later reactivated in the Permian.

Mesozoic ages

Mesozoic K-~~–~~Ar ages were obtained for the Snøfjorden-~~–~~Slatten fault on the Porsanger Peninsula (sample 7; Figure 1~~Figure 1~~ &~~&~~and Figure 2~~Figure 2~~g), which yielded Middle (238.0 ± 5.4 Ma) ~~–~~ Late Triassic (227.4 ± 5.3 Ma) to Hettangian (earliest Jurassic; 200.4 ± 6.0 Ma) ages (Table 2~~Table 2~~, Figure 4~~Figure 4~~ &~~&~~and Figure 6~~Figure 6~~). This sample, however, contains minor K-feldspar in the coarse and intermediate grainsize fractions, which may have induced an excess of potassium, hence yielding ages younger ~~ages~~ than the actual age of faulting (Lovera et al., 1989). Nonetheless, the Hettangian age obtained for the finest fraction seems reasonable and most likely reflects syn-kinematic crystallization during an actual faulting event.

Fault gouge of the coarse, intermediate and fine grainsize fractions of sample 1 taken near the Sørkjosen fault segment of the LVF (Figure 1~~Figure 1~~ &~~&~~and Figure 2~~Figure 2~~c) yielded a latest Triassic (Rhaetian) age of 206.8 ± 2.6 Ma, and Late Jurassic (late Kimmeridgian) ages of 153.2 ± 3.7 Ma and 153.4 ± 1.9 Ma, respectively (Table 2~~Table 2~~, Figure 4~~Figure 4~~ &~~&~~and Figure 6~~Figure 6~~), possibly suggesting that this fault splay of the LVF formed in the latest Triassic and was reactivated in the Late Jurassic. Similar K-~~–~~Ar ages were obtained for another splay fault of the LVF in Sørkjosen (sample 2; Figure 1~~Figure 1~~ &~~&~~and Figure 2~~Figure 2~~d), i.e~~.~~.. Olenekian 247.6 ± 3.7 Ma and 249.4 ± 3.3 Ma (Early Triassic) ages for the coarse and intermediate fractions and a latest Mid Jurassic age of 164.4 ± 4.5 Ma for the finest fraction (Table 2~~Table 2~~, Figure 4~~Figure 4~~ &~~&~~and Figure 6~~Figure 6~~). Similarly to the other fault in Sørkjosen (sample 1), it is possible that the gouge in sample 2 formed in the Early Triassic and was reactivated during the Mid Jurassic (Table 2~~Table 2~~, Figure 4~~Figure 4~~ &~~&~~and Figure 6~~Figure 6~~). However, a minor K-feldspar content observed in the diffraction ~~spectrums~~spectra of all three grainsize fractions of both of these faults

~~suggest~~suggests that the K-–Ar ages probably post-date the actual faulting, but it is uncertain by how much time (Table 1~~Table 1~~ &and Appendix A).

5. Discussion

We combine mineral assemblages in cohesive and non-cohesive fault-rocks to reconstruct the faulting and burial-–exhumation history of the NW Finnmark margin, using an average geothermal gradient of 30°C/km~~,~~ based on well data in adjacent portions of the SW Barents Sea (Bugge et al., 2002; Chand et al., 2008; Vadakkepuliyambatta et al., 2015), and utilizing the K-–Ar dating results of authigenic illites in non-cohesive fault-rocks to constrain the timing of faulting. The discussion starts with the estimated p-/T conditions and the Mesoproterozoic-–Neoproterozoic K/–Ar ages obtained for the Altafjorden faults 1 &and 2, and proceeds with mid-–late Paleozoic, and, finally, Mesozoic exhumation (p/T) and faulting data obtained from the LVF and TKFZ as basis for comparison with p-/T constraints and K/–Ar faulting ages from in Western Troms.

5.1. Mesoproterozoic-–Neoproterozoic faulting and exhumation history

5.1.1. Evolution of temperature conditions in Precambrian rocks

Microtextural and mineralogical analysis of cohesive fault-rocks along the Altafjorden faults 1 &and 2 (Figure 2~~Figure 2~~a &and b) show that brittle faulting initiated with the formation of quartz- and calcite-rich cataclasites (Figure 3~~Figure 3~~b &and c). On the one hand, quartz-rich cataclasite derived from a foliated~~, meta-~~ psammitic host-–rock with quartz/feldspar sigma-clasts (Figure 2~~Figure 2~~a &and b and Figure 3~~Figure 3~~a). On the other hand, calcite-cemented cataclasite ~~often~~commonly incorporate crystals with type II and IV twinning, which indicate that these crystals were subjected to temperature ranges of 150-–300°C (i.e~~.~~., 5-–10 km depth) and > 250°C (depth > 8 km) respectively (Figure 3~~Figure 3~~c; ~~Lerman, 1999~~Ferrill, 1991; Burkhard, 1993).

Quartz-rich and calcite-cemented cataclasites are truncated and ~~occasionally~~, in places, incorporated into subsequent iron/clay-rich cataclasites (Figure 3~~Figure 3~~b &and c). XRF analyses of non-cohesive fault-rocks sampled along the Altafjorden faults 1 &and 2 (samples 3 &and 4) show a dominance of smectite (Table 1~~Table 1~~ &and Appendix A), which suggests that the dominant clay mineral in related iron/clay-rich cohesive fault-rock shown in Figure 3~~Figure 3~~b is

smectite. Considering such a predominance of authigenic smectite in both non-cohesive and cohesive, iron/clay-rich fault-rocks (Figure 3~~Figure 3~~b, Table 1~~Table 1~~ &~~and~~ Appendix A), and assuming a complete diagenetic transformation of smectite into illite at ca. 105°C (~~cf.~~ Morley et al., 2018) and a complete absence of authigenic illite at temperature < 35°C (Eberl et al., 1993), we propose that clay-rich fault-rocks along brittle faults in the Alta-~~–~~Kvænangen tectonic window formed at temperature conditions comprised between 35-~~–~~105°C (i.e.~~.~~, 1-~~–~~3.5 km depth). Although ~~crosscutting~~cross-cutting relationships of calcite-rich cataclasite with quartz- and iron/clay-rich fault-rocks are unknown, the irreversibility of the diagenetic transformation of smectite into illite (Eberl et al., 1993) suggests that calcite-cemented cataclasite, which formed at 5-~~–~~10 km depth, is older than the iron/clay-rich (cohesive and non-cohesive) fault-rocks, which formed at shallow depth 1-~~–~~3.5 km. Hence, we argue that Precambrian basement rocks in Altafjorden experienced at least three brittle faulting events, starting with quartz-rich cataclasite (Figure 3~~Figure 3~~b) and/or calcite-cemented cataclasite formed at a depth of 5-~~–~~10 km (~~Lerman, 1999~~Ferrill, 1991; Burkhard, 1993; Figure 3~~Figure 3~~c). ~~Then~~Subsequently, basement rocks were exhumed to a shallow crustal level < 3.5 km (Morley et al., 2018) when the final, iron- and smectite-rich faulting event occurred (Figure 3~~Figure 3~~b).

5.1.2. Timing of faulting and exhumation of Precambrian rocks

The latest Mesoproterozoic (ca. 1050 Ma) – early Neoproterozoic ages (ca. 945 Ma) obtained for the coarse fraction of sample 3 and the coarse and intermediate fractions of samples 4 (Table 2~~Table 2~~, Figure 4~~Figure 4~~ &~~and~~ Figure 5~~Figure 5~~), and the slickenside lineations and drag-folded foliation indicating down-~~to the~~-NNW normal motions along both faults (Figure 2~~Figure 2~~a &~~and~~ b) suggest that the Altafjorden faults 1 &~~and~~ 2 contributed to the initial stages of formation of the NW Baltoscandian basins (Siedlecka et al., 2004; Nystuen et al., 2008) during the rifting of the Asgard Sea (Cawood et al., 2010; Cawood &~~and~~ Pisarevsky, 2017). Possible driving mechanisms for the formation of these basins and faults are a far-field influence of the coeval, basin-oblique/orthogonal, Sveconorwegian contraction, i.e.~~.~~, a formation as impactogenic rift-basins (Barberi et al., 1982), and/or a possible influence of late/post-orogenic collapse of the Sveconorwegian Orogeny (Bingen et al., 2008; Viola et al., 2013). The latest Mesoproterozoic-~~–~~early Neoproterozoic ages (ca. 1050-~~–~~945 Ma) obtained on illite in coarsest and intermediate fractions of brittle fault-rocks (Table 2~~Table 2~~, Figure 4~~Figure 4~~ &~~and~~ Figure 5~~Figure 5~~)), which

we interpreted as syn-kinematic crystallization ages, suggest that basement rocks of the Alta-Kvænangen tectonic window were already exhumed above the brittle-ductile transition at that time, and may provide a maximum estimate for the age of quartz- and calcite-rich cataclasites formed at depth of 5-10 km along these faults (Figure 3Figure 3b &and c).

The finest fractions of both samples and intermediate fraction of sample 3 of non-cohesive fault-rocks in basement rocks yielded mid-Neoproterozoic ages (ca. 825-810 Ma; Table 2Table 2, Figure 4Figure 4 &and Figure 5Figure 5).), which we interpreted as crystallization ages. Combining these ages with normal shear-sense indicators observed in the field (Figure 2Figure 2a &and b), we propose that they represent the onset of rifting of the Iapetus Ocean-Ægir Sea during the breakup of Rodinia between 825 and 740 Ma (Torsvik &and Rehnström, 2001; Hartz &and Torsvik, 2002; Li et al., 2008). Similar Neoproterozoic K/Ar ages of ca. 790-780 Ma and 740-735 Ma are reported from dating of authigenic illite/muscovite along the Kvenklubben and Porsavannet faults in the adjacent Repparfjord-Komagfjord tectonic window in NW Finnmark (Torgersen et al., 2014; Figure 1Figure 1).

The Altafjorden faults 1 &and 2, although located close and oriented sub-parallel to Caledonian thrust faults (e.g.., the Talvik fault; Figure 2Figure 2e) and major, post-Caledonian normal faults (e.g.., the LVF; Figure 1Figure 1), were most likely not reactivated after ca. 810 Ma (mid-Neoproterozoic; Table 2Table 2, Figure 4Figure 4 &and Figure 5Figure 5), as subsequent faulting would have triggered younger mineral assemblages and ages. Possible explanations for the non-reactivation of these faults include a north/westwards- to west-wards (basinwards?) migration of rifting to areas adjacent to the LVF, e.g.., the Kvenklubben and Porsavannet faults dated at ca. 790-735 Ma (Torgersen et al., 2014), and to faults in Troms) and northern Finnmark, where Ediacaran metadolerite dykes intruded basement rocks during the breakup of the Iapetus Ocean-Ægir Sea (Zwaan &and van Roermund, 1980; Siedlecka et al., 2004; Nasuti et al., 2015). The lack of reactivation of Altafjorden faults 1 &and 2, predominance of authigenic smectite clay mineral in non-cohesive fault-rock (samples 3 &and 4 in Table 1Table 1 &and Appendix A) and the irreversibility of smectite-illite transformation (Eberl et al., 1993) suggest that Precambrian rocks of the Alta-Kvænangen tectonic window were exhumed and have remained at shallow depth < 3.5 km since the mid-Neoproterozoic (ca. 825 Ma; Table 2Table 2, Figure 4Figure 4 &and Figure 5Figure 5). This conclusion is supported by predominance and preservation of authigenic smectite

in similar non-cohesive fault-rocks in the Repparfjord–Komagfjord tectonic window (Torgersen et al., 2014).

Exhumation rates during latest Mesoproterozoic–early Neoproterozoic normal faulting are unknown. However, exhumation rate from the early (ca. 945 Ma and 5–10 km depth) to mid-Neoproterozoic (ca. 825 Ma and 1–3.5 km depth) were probably in the range of ca. 10–75 m per MaMyr, i.e., comparable to what is expected from average continental erosion rates (10–100 m per MaMyr; Schaller et al., 2002; Eppes &and Keanini, 2017 – their figure 5). This therefore suggests a period of tectonic quiescence between opening of the Asgard Sea (first two, quartz/calcite-rich faulting events) and the onset of Iapetus rifting (final, smectite-rich faulting event).

5.2. Phanerozoic faulting and exhumation history

5.2.1. Evolution of temperature conditions in Caledonian rocks

We described five types of cohesive cataclastic fault-rocks in NW Finnmark based on mineralogical and textural descriptions. First, epidote- and chlorite-rich, stilpnomelane-bearing cataclasite (Figure 3Figure 3e &and h–j) formed by faulting of Caledonian mafic schists and gneisses (amphibolites; Figure 3Figure 3d &and e; Ramsay et al., 1979; 1985; Gayer et al., 1985)) and is consistently truncated by and incorporated into the other four types of cataclasites (Figure 3Figure 3e &and h–j), suggesting that epidote/chlorite-rich cataclasites correspond to the earliest stage of brittle faulting recorded by Caledonian rocks. The epidote + chlorite + stilpnomelane ± biotite mineral assemblages present both in the epidote/chlorite-rich cataclasites and adjacent host rocks, where biotite is almost completely recrystallized into chlorite (Figure 3Figure 3d), indicate lower greenschist–facies conditions during this faulting event, which constrain the minimum temperature during faulting to ca. 300°C (i.e., 10 km depth). Further, rounded clasts of stilpnomelane in epidote-rich cataclastic veins onshore Magerøya (Figure 3Figure 3h &and k) suggest faulting temperatures at prehnite–pumpellyite- to lower greenschist–facies conditions comprised between 300°C and 470°C (Miyano &and Klein, 1989), i.e., a depth range of 10–16 km, which is consistent with pseudosection thermobarometry and U–Pb ages on titanite

Formatted: Font: 12 pt, Not Bold

Formatted: Font: 12 pt, Not Bold

Formatted: Font: 12 pt, Not Bold

Formatted: Font: 12 pt, Not Bold

constraining retrograde Caledonian shearing < 550°C (i.e., < 18 km depth) in the Kalak Nappe Complex in northern Troms to 440–420 Ma (Silurian; Gasser et al., 2015).

The second type of cataclasite corresponds to very fine-grained, quartz-rich cataclasite and veins of recrystallized quartz that ~~often~~commonly truncate and incorporate clasts of (type 1) epidote- and chlorite-rich cataclastic veins (Figure 3~~Figure 3~~e ~~&~~and h). Since quartz dissolution only occurs at temperatures > 90°C (Worley ~~&~~and Tester, 1995) and deforms plastically at temperature > 300°C (Tullis and Yund, 1977; Scholz, 1988; Hirth ~~&~~and Tullis, 1989), we argue that the quartz-rich cataclasite and associated quartz veins were formed during a discrete, second faulting event at ~~depth comprised~~depths between 3 and 10 km. The transition from early, deep (10–16 km), epidote/chlorite-rich faulting to subsequent, shallower (3–10 km) quartz-rich cataclasis indicates that Caledonian rocks were partly exhumed between the two faulting events.

The third type of cataclasite is made up of widespread calcite both as clasts, cement and precipitations (Figure 3~~Figure 3~~e ~~&~~and i). This type of cataclasite ~~crosscuts~~cross-cuts epidote/chlorite- (type 1) and quartz-rich cataclasites (type 2), hence suggesting calcite-rich cataclasite (type 3) formed during a younger (reactivation) faulting event (Figure 3~~Figure 3~~e ~~&~~and i). Since calcite crystals of the cataclasite display characteristic twinning type I and II (Figure 3~~Figure 3~~i), we inferred a temperature range of 150–200°C (~~Lerman, 1999~~Ferrill, 1991; Burkhard, 1993) and a depth of 5–7 km during this tentative, third faulting event.

A fourth type of cataclasite is present along fault segments of the LVF and TKFZ, showing pervasive laumontite clasts and precipitations (Figure 3~~Figure 3~~m), and consistently truncates greenschist–facies cataclasites (types 1, 2 ~~&~~and 3). Laumontite crystals ~~are~~ commonly are undeformed and ~~often~~ appear as elongated crystals with their long axis perpendicular to fracture boundaries (Figure 3~~Figure 3~~m). These observations suggest that laumontite formed as late growth along opening extensional cracks or in tension veins, most likely at a later stage of faulting than minerals in the greenschist–facies cataclasites. Laumontite crystals themselves ~~often~~commonly appear mildly cataclased (Figure 3~~Figure 3~~e, l ~~&~~and m), thus indicating that faulting persisted after the growth of laumontite. The temperature stability range of laumontite is 50–230°C (Jové ~~&~~and Hacker, 1997), which suggests that syn~~/~~–post-laumontite faulting occurred at a depth range of ca. 2–8 km, i.e.~~.~~., probably shallower than faulting event associated with epidote/chlorite- (type 1), quartz- (type 2) and calcite-rich (type 3) cataclasites.

Formatted: Font: 12 pt, Not Bold

Formatted: Font: 12 pt, Not Bold

Formatted: Font: 12 pt, Not Bold

Formatted: Font: 12 pt, Not Bold

Formatted: Font: 12 pt, Not Bold

The fifth type of cataclasite is composed of iron oxide and clay minerals that ~~crosscut~~cross-cut all other cataclasite types and vein minerals (Figure 3~~Figure 3~~h, l ~~&~~and n). XRF analyses of related non-cohesive fault-rock show a consistent dominance of authigenic smectite with subsidiary mixed-layer chlorite-~~–~~smectite and minor illite (Table 1~~Table 1~~ ~~&~~and Appendix A), suggesting that the dominant clay mineral observed in the fifth type of cohesive cataclastic fault-rocks is smectite. Based on the preservation of abundant authigenic smectite ~~(cf.~~ (Table 1~~Table 1~~ ~~&~~and Appendix A) and on the irreversibility of the smectite-~~–~~illite diagenetic transformation (Eberl et al., 1993), we propose that the ultimate (fifth) faulting event(s) in Caledonian rocks in NW Finnmark occurred at temperatures < 105°C (Morley et al., 2018), i.e~~.~~., depth < 3.5 km, and that Caledonian rocks have remained at such shallow depth through Mesozoic-~~–~~Cenozoic times.

Locally, XRF analysis of cohesive fault-rocks along WNW-~~–~~ESE ~~trending~~ striking fault segments of the TKFZ in western Magerøya (sample 10; Figure 1~~Figure 1~~) show almost pure authigenic smectite (Table 1~~Table 1~~ ~~&~~and Appendix A). This constrains temperature during faulting to a minimum of 35-~~–~~65°C (ca. 1-~~–~~2 km depth) at which small amounts of illite may form (Eberl et al., 1993; Huang et al. 1993; Morley et al., 2018). Shallow faulting is further supported by the presence of mixed-layer chlorite-~~–~~smectite clays (in samples 1, 2, 6 ~~&~~and 8; Table 1~~Table 1~~ ~~&~~and Appendix A), which suggests that smectite (and mixed-layer chlorite-~~–~~smectite) authigenic clays formed by retrograde diagenesis (i.e~~.~~., exhumation) of crushed chlorite during faulting (Warr ~~&~~and Cox, 2001; Nieto et al., 2005; Haines ~~&~~and van der Pluijm, 2012). Thus, we argue that Caledonian rocks along the LVF and TKFZ experienced another (late-stage) phase of uplift/faulting and exhumation from zeolite-~~–~~facies conditions (2-~~–~~8 km) to diagenetic conditions (1-~~–~~3.5 km). Alternatively, chlorite-~~–~~smectite in non-cohesive fault-rocks along fault-segments of the LVF (e.g~~.~~., samples 1 ~~&~~and 2; Figure 1~~Figure 1~~, Table 1~~Table 1~~ ~~&~~and Appendix A) formed during the shallowest phase of smectite-~~–~~illite clay mineral reaction, while interlayered illite-~~–~~smectite (~~cf.~~ sample 8; Table 1~~Table 1~~ ~~&~~and Appendix A) formed during deeper phases of this reaction due to higher, normal faulting-related burial in the hanging-~~–~~wall of the LVF (Whitney ~~&~~and Northrop, 1988). However, more samples are needed in the hanging-~~–~~wall of the LVF to verify this hypothesis (only sample 8; Figure 1~~Figure 1~~).

Late Paleozoic inversion of brittle- –ductile Caledonian thrusts

The coarse fraction of the Talvik fault (sample 5; Figure 1Figure 1), a south-verging Caledonian thrust in rocks of the Kalak Nappe Complex in Altafjorden, yielded a mid/late Silurian age (427.3 ± 8.4 Ma) suggesting that brittle faulting along this fault initiated during the latest stagesstage (Scandian) of the Caledonian Orogeny (Table 2Table 2, Figure 4Figure 4 &and Figure 6Figure 6). Movement along the Talvik fault started with top-to the south, ductile Caledonian thrusting as shown by quartz sigma-clasts and shear bands in mylonitic foliation, likely at a depth > 10 km (Tullis and Yund, 1977; Scholz, 1988; Hirth &and Tullis, 1989), and continued with down-to the north, brittle, normal dip-slip faulting truncating ductile fabrics (Figure 2Figure 2e). The earliest evidenceindications of late/ –post-Caledonian, normal faulting in northern Norway are Early Devonian ages obtained for inverted shear zones in Vesterålen (Steltenpohl et al., 2011). This suggests that the mid/ –late Silurian faulting age/event recorded along the Talvik fault (crystallization age of coarse fraction) might represent a phase of top-to the south, brittle (-ductile?), Caledonian brittle thrusting, rather than late/ –post-Caledonian normal faulting (Figure 2Figure 2e). This is consistent with thermobarometry and U–Pb ages constraining Caledonian retrograde shearing at temperature < 550°C to the Silurian at ca. 440–420 Ma (Gasser et al., 2015). Exhumation of the Talvik fault to brittle depth < 10 km in the mid/ –late Silurian was most likely due to combined thrusting and erosion. Alternatively, thisthe obtained Silurian age reflectsmay reflect input from an inherited illite/muscovite component as shown by a small illite peak with epizonal KI (< 0.25) in the coarse fraction of this sample (Appendix A), suggesting athat brittle faulting event younger than theinitiated after Silurian times.

Top-to the south, Silurian, brittle thrusting along the Talvik fault was followed by successive early Carboniferous (Tournaisian), 353.7 ± 4.1 Ma and early Permian, 282.1 ± 6.3 Ma faulting events obtained from the intermediate and finest gouge fractions respectively (Table 2Table 2, Figure 4Figure 4 &and Figure 6Figure 6).) and interpreted as syn-kinematic crystallization ages. These events likely reflect post-Caledonian, down-to the Nnorth reactivation as a normal fault during the collapse of the Caledonides. Extensional reactivation is supported by normal dip-slip slickensides along the Talvik fault truncating the initial ductile fabrics (Figure 2Figure 2e). Further support appears from the early Permian inversion of an analog Caledonian thrust in the Repparfjord- –Komagfjord tectonic window, the Kvenklubben fault (Torgersen et al., 2014), and from offshore seismic studies on the Finnmark Platform, where a major Caledonian

thrust, the Sørøya–Ingøya shear zone, was inverted in the Mid-Middle to Late Devonian–early Carboniferous (Figure 1Figure 1; Koehl et al., 2018).

Late Paleozoic normal faulting

Our dating efforts of brittle segments of the LVF and TKFZ outlined above revealed numerous and consistent, late Paleozoic ages (Table 2Table 2, Figure 4Figure 4 &and Figure 6Figure 6). Obtained K–Ar syn-kinematic crystallization ages cover a time span from early Carboniferous (Tournaisian; one age) for the Talvik fault, late Carboniferous (three ages) for brittle faults on the Porsanger Peninsula and Magerøya (samples 8, 9 &and 10; Figure 4Figure 4 &and Figure 6Figure 6), to early–mid Permian (eight ages for samples 5, 6, 8, 9 &and 10; Figure 4Figure 4 &and Figure 6Figure 6). By comparison, early (four ages) to late (one age) Carboniferous K–Ar ages were reported for the Markopp fault, and (two) early Permian ages for the Kvenklubben fault in nearby rocks of the Repparfjord–Komagfjord tectonic window (Torgersen et al., 2014). In addition, the Laksvatn fault in Western Troms (Figure 1Figure 1) yielded two Late Devonian ages (Davids et al. 2013). This down-to the-NW normal fault is interpreted as a major, inverted Caledonian thrust possibly merging with the southwestern continuation of the LVF (Koehl et al., submitted), thus suggesting that post-Caledonian, normal brittle faulting along the LVF initiated in the Late Devonian. Further support of Devonian faulting is found offshore, where potential Mid-Middle–Late Devonian sedimentary rocks were deposited along inverted Caledonian thrusts on the Finnmark Platform–west, and where the offshore segments of the LVF on the western Finnmark Platform east (Koehl et al., 2018) bound a major (half-) graben filled with Carboniferous (Bugge et al., 1995) and, conceivably, latestuppermost Devonian clastic sedimentary deposits (Roberts et al., 2011).

The dated faults in the Porsanger Peninsula (sample 8; Figure 2Figure 2h), Talvik (sample 5; Figure 2Figure 2e) and Storekorsnes (sample 6; Figure 2Figure 2f) show down-to the-north, normal dip-slip to oblique-slip movements, suggesting that they are all related to late Paleozoic, post-Caledonian extension. The long time-spread of the obtained late Paleozoic, post-Caledonian K/Ar, K–Ar syn-tectonic crystallization ages (Table 2Table 2, Figure 4Figure 4 &and Figure 6Figure 6) suggests either a long-term progressive, or two discrete faulting periods. From our results, we favor two discrete periods, one in the Late Devonian–early Carboniferous at ca. 375–325 Ma (based on one age in this study, four from Torgersen et al., 2014 and two from Davids et

al., 2013) and one in the late Carboniferous–mid Permian at ca. 315–265 Ma (eleven ages from the present study and two from Torgersen et al., 2014).

The obtained earliest Permian (Asselian) syn-kinematic crystallization ages for three different fractions of the same cataclasite in the fault in the hanging-wall of the LVF on the Porsanger Peninsula (sample 8, Figure 1~~Figure 1~~, Table 2~~Table 2~~, Figure 4~~Figure 4~~ &and Figure 6~~Figure 6~~), verified within two-sigma error range, may reflect a single faulting event. The short time span suggests that the fault was not reactivated later, since further faulting would have been recorded in the finest grainsize fraction. This conclusion is supported by offshore seismic data on the Finnmark Platform, showing that the thickness of Permian sedimentary rocks is constant across brittle normal faults, such as the LVF and Måsøy Fault Complex (Figure 1~~Figure 1~~), and that most brittle faults die out within the Carboniferous and lower part of the Permian sedimentary successions (Koehl et al., 2018). However, offshore seismic data on the Finnmark Platform suggest that early–mid Permian, K~~/~~–Ar ages (Table 2~~Table 2~~, Figure 4~~Figure 4~~ &and Figure 6~~Figure 6~~ and Torgersen et al., 2014) obtained onshore NW Finnmark may represent only minor tectonic adjustments rather than major faulting events (Koehl et al., 2018). Thus, an alternative interpretation for the dominance of Permian ages is due to partial overprinting/resetting of authigenic illite from the main early ~~(~~–(–late?) Carboniferous faulting period.

Of the five dated faults that yielded late Paleozoic, post-Caledonian ages (samples 5, 6, 8, 9 &and 10; Table 2~~Table 2~~ &and Figure 4~~Figure 4~~), only two of them included cohesive fault-rock (samples 5 &and 6; Figure 1~~Figure 1~~). For those that only comprised non-cohesive gouge (samples 8, 9 &and 10) with predominance of authigenic smectite clay mineral and subsidiary authigenic illite (Table 1~~Table 1~~ &and Appendix A), it seems reasonable to conclude that faulting occurred at shallow depth between 1– and 3.5 km (Eberl et al., 1993; Morley et al., 2018) in the late Carboniferous–mid Permian (Figure 4~~Figure 4~~ &and Figure 6~~Figure 6~~). The other two faults that yielded late Paleozoic ages (samples 5 &and 6; Figure 1~~Figure 1~~) and comprise both cohesive and non-cohesive fault-rocks (Figure 2~~Figure 2~~e &and f), likely formed at deeper crustal levels and higher p/T conditions. Non-cohesive fault-rocks along the Talvik fault (sample 5), consisting of authigenic smectite with minor illite, yielded early Carboniferous (intermediate fraction) and early Permian (finest fraction) ages (Table 2~~Table 2~~), while cohesive fault-rocks along this fault are characterized by both quartz- and calcite-rich cataclasites (types 2 &and 3). These data, backed by ~~crosscutting~~cross-cutting relationships between quartz-, calcite- and clay-rich cohesive fault-rocks

(types 2, 3 ~~&~~and 5; Figure 3~~Figure 3~~e), suggest that quartz- and calcite-rich cataclasites (types 2 ~~&~~and 3) along the Talvik fault formed in the Late Devonian (?) ~~–~~– early Carboniferous at a depth range of ca. 3~~–~~–10 km (Scholz, 1988; Hirth ~~&~~and Tullis, 1989; Ferrill, 1991; Burkhard, 1993; Worley ~~&~~and Tester, 1995~~; Lerman, 1999~~). Later on, these cataclasites were overprinted by non-cohesive, smectite-rich, cohesive (type 5) and non-cohesive fault-rocks generated at depth of 1~~–~~–3.5 km in the early Permian (Figure 6~~Figure 6~~; Eberl et al., 1993; Morley et al., 2018). These data are consistent with a partial exhumation of the Talvik fault and nearby Caledonian host rocks from the early Carboniferous to early Permian, with average exhumation rate along this fault varying from < 185 (Silurian~~–~~–early Carboniferous) to < 125 m per ~~Ma~~Myr (early Carboniferous~~–~~–early Permian).

Similarly, for the fault in Storekorsnes, the intermediate and finest fractions of smectite-dominated, fault-gouge sample 6 (Figure 1~~Figure 1~~, Table 1~~Table 1~~ ~~&~~and Appendix A) yielded latest Carboniferous~~–~~–early Permian ages (Table 2~~Table 2~~ ~~&~~and Figure 4~~Figure 4~~), and the fault comprises epidote- (type 1), quartz- (type 2), zeolite- (type 4) and smectite/chlorite~~–~~–smectite~~–~~rich (type 5) cohesive fault-rocks (Figure 3~~Figure 3~~e). The obtained K~~/~~–Ar ages, kinematic, down~~-to-the~~-NW, normal dip-slip character (Figure 2~~Figure 2~~f) and stability field of smectite suggest that smectite- and chlorite/smectite-rich cohesive and non-cohesive fault-rocks found along this fault formed during normal faulting in the latest Carboniferous~~–~~–early Permian at depth of 1~~–~~–3.5 km (Eberl et al., 1993; Morley et al., 2018). Epidote-rich and stilpnomelane-bearing (type 1), and quartz- (type 2) and zeolite-rich (type 4) cataclasites are all ~~crosscut~~cross-cut by smectite-rich (cohesive and non-cohesive) fault-rocks (Figure 3~~Figure 3~~e) and reflect deeper faulting depths (ca. 2~~–~~–10 km; Scholz, 1988; Hirth ~~&~~and Tullis, 1989; Miyano ~~&~~and Klein, 1989; Ferrill, 1991; Burkhard, 1993; Worley ~~&~~and Tester, 1995; Jové ~~&~~and Hacker, 1997~~; Lerman, 1999~~). Thus, we propose that cataclasites type 1, 2 and 4 formed much earlier, possibly in the Late Devonian~~–~~–early Carboniferous as suggested by K~~/~~–Ar dating along the Laksvatn (Davids et al., 2013) and Talvik fault (Table 2~~Table 2~~ ~~&~~and Figure 4~~Figure 4~~), and were later exhumed and overprinted by late Carboniferous~~–~~–early Permian, smectite-rich faulting. Tentative driving mechanisms for exhumation may have been an interplay between normal faulting, footwall uplift and continental erosion. This is supported by extensive normal faulting offshore, in ~~(Late~~Middle to Upper Devonian~~?)~~ (?) – Carboniferous rocks, and by the presence of a major, mid-Carboniferous erosional

unconformity of pre-Pennsylvanian rocks on the Finnmark Platform (Larssen et al., 2002; Koehl et al., 2018).

Of importance in restoring the exhumation history of NW Finnmark is that authigenic smectite is particularly dominant in non-cohesive fault-rocks in the footwall and along fault segments of the LVF, although ~~often~~generally associated ~~to high~~with large amounts of chlorite along fault segments of the LVF (e.g~~.~~., Talvik fault and Sørkjosen faults; see samples 1, 2 ~~&~~and 5 in Table 1~~Table 1 &~~and Appendix A), whereas interlayered illite~~–~~–smectite dominates in non-cohesive fault-rocks in the hanging~~-~~ wall of the LVF, e.g~~.~~., sample 8 ~~(cf. (~~Figure 1~~Figure 1~~, Table 1~~Table 1 &~~, and Appendix A). A plausible interpretation is that km-scale, post-Caledonian downthrow to the northwest along the LVF (partly) enhanced the exhumation of brittle faults and Caledonian rocks in the footwall, while hanging~~-~~ wall segments of the LVF remained at deeper levels, producing interlayered illite~~–~~–smectite (~~cf. sample~~ 8; Table 1~~Table 1 &~~, and Appendix A), a deeper end-member product of the smectite~~–~~–illite reaction (Whitney ~~&~~and Northrop, 1988). This conclusion may be partly falsified by the illite~~–~~–smectite~~–~~rich composition of fault-gouges along the Porsavannet and Markopp faults in the footwall of the LVF (Torgersen et al., 2014). However, these faults yielded significantly older ages (respectively mid Neoproterozoic~~–~~–mid Paleozoic and early Carboniferous) than the late Carboniferous~~–~~–early/mid Permian ages of smectite/chlorite~~–~~–smectite~~–~~rich fault-rocks from our study (Table 2~~Table 2~~). It is therefore possible that the authigenic, interlayered illite~~–~~–smectite in fault-rocks along the Porsavannet and Markopp faults reflect earlier, deeper faulting periods.

Furthermore, XRF analyses of fault gouge from a segment of the TKFZ in western Magerøya (sample 10; Figure 1~~Figure 1~~ ~~&~~and Figure 2~~Figure 2~~j), yielding late Carboniferous to mid-Permian K~~–~~–Ar ages ~~(cf. (~~Table 2~~Table 2~~, Figure 4~~Figure 4~~ ~~&~~and Figure 6~~Figure 6~~), show almost pure authigenic smectite ~~(cf. (~~Table 1~~Table 1~~ ~~&~~and Appendix A). This suggests that Permian faulting occurred at very low temperature of 35~~–~~–65°C (Eberl et a., 1993; Huang et al., 1993; Morley et al. 2018), i.e~~.~~., depth of ca. 1~~–~~–2 km, and remained at shallow crustal levels until present, thus preventing transformation of smectite to illite through diagenesis. Late Paleozoic exhumation and shallow faulting in NW Finnmark and along other portions of the Barents Sea margin, e.g~~.~~., Lofoten~~–~~–Vesterålen, are supported by Apatite Fission Track data, indicating that ~~outcropping~~exposed rocks northern Norway have remained at relatively low temperature < 120°C, i.e~~.~~., depth < 4 km, since mid-Permian times (Hendriks et al., 2007).

Considering K/Ar–Ar syn-kinematic crystallization ages obtained on non-cohesive fault-rocks, and mineral assemblages and crosscuttingcross-cutting relationships of the five types of cohesive fault-rocks, we estimate exhumation rates from the Silurian (ca. 425 Ma and 10–16 km depth) to Late Devonian (ca. 375 Ma and minimum 5–10 km depth) to be < 220 m per MaMyr, i.e.., analogous to estimate along the Talvik fault (< 185 m per MaMyr). Similarly, exhumation rates through the Late Devonian (ca. 375 Ma and minimum 5–10 km depth) – early Carboniferous (ca. 325 Ma and 2–8 km depth) faulting period were < 160 m, and < 115 m per MaMyr through the ultimate faulting period from the end of the early Carboniferous (ca. 325 Ma and maximum 2–8 km depth) to the mid-Permian (ca. 265 Ma and 1–3.5 km depth), i.e.., similar to exhumation rates obtained along the Talvik fault (< 125 m per MaMyr). Decreasing exhumation rate from Silurian to mid-Permian times might indicate progressively milder faulting activity along the margin, with exhumation rates in the late Carboniferous–mid Permian being comparable/slightly higher than average continental erosion rates thought to be in the order of 10–100 m per MaMyr (Schaller et al., 2002; Eppes &and Keanini, 2017 – their figure 5). Thus, we propose that exhumation in the Silurian–early Carboniferous was driven by a combination of continental erosion, thrusting and, later on, normal faulting, while exhumation in the late Carboniferous–mid Permian was mostly due to continental erosion with only a limited contribution of normal faulting.

Alternatively, the predominance of Permian faulting ages obtained onshore NW Finnmark may be attributed to a period of extensive weathering in the (late Carboniferous– ?) early–mid Permian (cf. (Table 2Table 2, Figure 4Figure 4 &and Figure 6Figure 6), possibly reflected by highly weathered host rocks and brittle fault surfaces showing no kinematic indicators onshore Magerøya (sample 9 &and 10; Figure 1Figure 1, and Figure 2Figure 2i &and j). Although this weathering may be related to much younger processes (Olesen et al., 2012;, 2013), Carboniferous–Permian, (sub-) tropical climate conditions prevailed in Baltica (Stemmerik, 2000; Larssen et al., 2002; Samuelsberg et al., 2003) and, hence, may have initiated weathering of exposed, uplifted footwall blocks along major faults like the LVF and Måsøy and Troms–Finnmark fault complexes offshore (Figure 1Figure 1). This is supported by widespread exhumation and erosional truncation of pre-Pennsylvanian rocks in the footwall of the Troms–Finnmark Fault Complex, on the Finnmark Platform (Koehl et al., 2018), linked to a mid-Carboniferous phase of eustatic sea-level fall (Saunders &and Ramsbottom, 1986). This exhumation/weathering event is also consistent with the Early Mesozoic, minimum age estimate of weathering of basement rocks along the Norwegian

continental shelf (Olesen et al., 2012~~;~~, 2013). Although the dated faults were still buried to depth > 1 km in the mid-Permian, as shown by the presence of (minor) authigenic illite (Eberl et al., 1993) used for K~~/~~–Ar age dating of the faults, field studies in onshore tunnels in Norway show that weathering processes related to percolation of acidic water may penetrate the bedrock > 200 m along fault surfaces (Olesen et al., 2012~~;~~, 2013), thus, making this alternative explanation possible, though unlikely. Another obstacle to this interpretation is the lack of a major erosional unconformity/truncation in upper Carboniferous~~–~~–lower/mid Permian sedimentary rocks on the Finnmark Platform offshore (Larssen et al., 2002; Samuelsberg et al., 2003; Koehl et al., 2018).

Mesozoic faulting

~~Reliable~~A reliable Mesozoic K~~/~~–Ar syn-tectonic crystallization age was ~~only~~ obtained only for the finest fraction of the Snøfjorden~~–~~–Slatten fault (sample 7; Figure 1~~Figure 1~~ ~~&~~and Table 2~~Table 2~~), yielding a Hettangian age. All the other faults yielding Mesozoic ages (all three fractions in samples 1 ~~&~~and 2, coarse fraction of sample 6, coarse and intermediate fractions of sample 7 and intermediate fraction of sample 9) comprise subsidiary K-feldspar (

Formatted: Font: Not Bold

Formatted: Font: Not Bold, Not Italic

Formatted: Font: Not Bold

Formatted: Font: Not Bold, Not Italic

970

Table 1~~Table 1~~ ~~&~~and Appendix A), which provided additional potassium and, thus, yielded younger ages than the actual age of faulting (Table 2~~Table 2~~; ~~cf.~~ red ages in Figure 4~~Figure 4~~). Thus, we disregard these ages because of their high uncertainty. Considering the ~~scarsity~~scarcity of Mesozoic-~~–~~Cenozoic ages, we argue that NW Finnmark, as well as adjacent offshore areas of the Finnmark Platform (Koehl et al., 2018) were tectonically quiet after late Paleozoic (Devonian-~~–~~mid Permian) extension and were only subjected to minor, local extensional faulting events, e.g.~~.~~., in the earliest Jurassic (Hettangian) for the Snøfjorden-~~–~~Slatten fault ~~(cf.~~ (Figure 1~~Figure 1~~, Table 2~~Table 2~~, Figure 4~~Figure 4~~ ~~&~~and Figure 6~~Figure 6~~) and Early Cretaceous for the Kvenklubben fault (Torgersen et al., 2014).

5.3. Regional implications

An implication of the latest Mesoproterozoic-~~–~~Neoproterozoic K~~/~~-~~–~~Ar ages obtained for the ENE-~~–~~WSW ~~trending~~ striking Altafjorden faults 1 ~~&~~and 2 in the Alta-~~–~~Kvænangen tectonic window is that they partly support the interpretation of Koehl et al. (submitted), suggesting that ENE-~~–~~WSW ~~trending~~ striking faults represent inherited Precambrian fault fabrics. However, the inferred normal sense of shear and latest Mesoproterozoic-~~–~~mid Neoproterozoic K~~/~~-~~–~~Ar faulting ages obtained for the Altafjorden faults 1 ~~&~~and 2 (Figure 2~~Figure 2~~a ~~&~~and b) suggest that these faults formed as extensional normal faults rather than conjugate strike-slip faults to WNW-~~–~~ESE ~~trending~~ striking faults like the TKFZ as suggested by Koehl et al. (submitted). Instead, latest Mesoproterozoic-~~–~~mid Neoproterozoic brittle faults might have provided preferentially oriented weakness zones for the formation of subparallel, subsequent and adjacent Caledonian thrusts (e.g.~~.~~., Talvik fault) and post-Caledonian normal faults (e.g.~~.~~., LVF; Figure 1~~Figure 1~~). Nevertheless, conjugate strike-slip faults ~~may exist in~~have been reported from NW Finnmark (Roberts, 1971; Worthing, 1984), but these display subvertical geometries and significant lateral displacement, and may have formed during (E-~~–~~W~~/~~- to) ENE-~~–~~WSW-~~–~~directed, Timanian contraction in the late Neoproterozoic, e.g.~~.~~., TKFZ (Siedlecka et al., 2004; Herrevold et al., 2009) and Akkarfjord fault (Roberts, 1971; Koehl et al., submitted).

Analogous studies of post-Caledonian brittle faults in Western Troms show that post-Caledonian extensional faulting initiated at depth > 10 km at greenschist-~~–~~facies conditions and

continued under pumpellyite–prehnite–facies conditions at depth < 8.5 km, thus supporting a gradual exhumation of the margin (Indrevær et al., 2013, 2014). More detailed mineralogic-textural analysis of clay-rich non-cohesive fault-rocks of the Vannareid–Burøysund, Sifjord and Laksvatn faults revealed dominance of smectite and chlorite clay minerals (Davids et al.., 2013), suggesting that brittle faults in Western Troms were exhumed to low temperature conditions (35–105°C; Eberl et al., 1993; Morley et al., 2018) and shallow depths (1–3.5 km) comparable the LVF and TKFZ in NW Finnmark. Furthermore, fault-gouge along the SSE-dipping Vannareid–Burøysund and Sifjord faults yielded similar early Carboniferous (intermediate fractions) and early Permian K/–Ar ages (finest fractions; Davids et al., 2013) compatible with the proposed Late Devonian–early Carboniferous and late Carboniferous–mid Permian stages of post-Caledonian brittle faulting in NW Finnmark (Table 2Table 2, Figure 4Figure 4, Figure 6Figure 6 and Torgersen et al., 2014).

A major contrast in K/–Ar ages in Western Troms and NW Finnmark is occurrence of latest Mesoproterozoic–mid Neoproterozoic ages for gouges of the southeasternmost normal faults within basement rocks of the Alta–Kvænangen tectonic window in NW Finnmark (Figure 4Figure 4 &and Figure 5Figure 5), while analogous faults in Archean–Paleoproterozoic rocks of the West Troms Basement Complex (Zwaan, 1995; Bergh et al., 2010) yielded Carboniferous–Permian ages (Davids et al., 2013). Another mild contrast is the occurrence of slightly younger, late Permian–Early Triassic, K/–Ar faulting ages for brittle faults in Western Troms (Davids et al., submitted), suggesting that extension migrated westwards after the late Carboniferous–mid Permian and persisted until the Early Triassic in coastal areas of Western Troms. Westwards younging of K/–Ar faulting ages is further supported by Mesozoic ages obtained for three faults in western Lofoten (Davids et al., 2013). Nonetheless, widespread Late Devonian–early Carboniferous and late Carboniferous–mid Permian ages in NW Finnmark, Western Troms and Lofoten–Vesterålen suggest that the main episode of extension and exhumation along the margin occurred in the late Paleozoic and was probably related to the collapse of the Caledonides (Davids et al., 2013, submitted; Torgersen et al., 2014; Koehl et al., 2018). Apatite Fission Track data in Western Troms and Lofoten–Vesterålen also indicate a period of rapid cooling (1–2°C/Ma per Myr) in the late Paleozoic, possibly due to combined extensive normal faulting and erosion, followed by a period of relatively slow cooling (< 0.2°C/Ma per Myr) in Mesozoic times, likely suggesting a tectonically quiet time period (Davids et al., 2013).

6. Conclusions

1) Three faulting events occurred in the latest Mesoproterozoic–mid Neoproterozoic (ca. 1050–810 Ma), including (i) latest Mesoproterozoic faulting (ca. 1050 Ma.) and (ii) an early Neoproterozoic faulting event (ca. 945 Ma) with quartz-rich and calcite-cemented cataclasites formed at depth of ca. 5–10 km, possibly reflecting the formation of the NW Baltoscandian basins during the opening of the Asgard Sea, and (iii) a shallow (depth 1–3.5 km), mid-Neoproterozoic faulting episode (ca. 825–810 Ma) with abundant authigenic smectite, related to the opening of the Iapetus Ocean–Ægir Sea and breakup of Rodinia between 825–740 Ma.

2) Exhumation rates estimates from 945 to 825 Ma were in the order of 10–75 m per ~~Ma~~Myr, thus indicating that continental erosion alone may account for early–mid Neoproterozoic exhumation and that tectonic quiescence prevailed between the opening of the Asgard Sea and the opening of the Iapetus Ocean–Ægir Sea.

3) The preservation of abundant authigenic smectite in cohesive and non-cohesive fault-rocks suggests that Paleoproterozoic basement rocks were exhumed to and remained at shallow crustal levels (< 3.5 km depth) since the mid-Neoproterozoic (ca. 825 Ma), and were not reactivated after mid-Neoproterozoic times despite being oriented parallel to major Caledonian thrusts and post-Caledonian normal faults.

4) Five faulting events occurred in Caledonian rocks, defining three faulting periods: (i) potential Silurian, top-~~to the~~ south thrusting along Caledonian thrusts (e.g.~~.~~., Talvik fault) initiated at a depth of 10–16 km, and was possibly associated with epidote/chlorite-rich, stilpnomelane-bearing cataclasis (type 1), (ii) widespread, Late Devonian–early Carboniferous (ca. 375–325 Ma) extensional faulting, occurred at decreasing depth and was accompanied by quartz-rich (type 2; 3–10 km depth), calcite-cemented (type 3; 5–7 km depth) and laumontite-rich cataclasites (type 4; 2–8 km depth) formed during three discrete faulting events possibly related to the collapse of the Caledonides, (iii) an ultimate, minor stage of shallow faulting in the late Carboniferous–mid Permian (ca. 315–265 Ma) dominated by iron/smectite/chlorite–smectite–rich, illite-bearing (type 5) fault-rocks formed at depth of 1–3.5 km, thus suggesting Caledonian rocks were progressively exhumed to near-surface depth in late Paleozoic times.

5) Km-scale, down-~~to the~~-NW normal faulting and footwall uplift along the ~~Langfjord-Vargsund~~Langfjorden–Vargsundet fault may be responsible for local variation of dominant, authigenic clay minerals in type 5 fault-rocks (1–3.5 km depth), producing deeper, interlayered illite–smectite in the hanging- wall and shallower, smectite and mixed-layer chlorite–smectite in the footwall.

6) Decreasing exhumation rates, < 220 m per ~~Ma~~Myr in Silurian–Late Devonian (425–375 Ma), < 160 m per ~~Ma~~Myr in Late Devonian–early Carboniferous (375–325 Ma) and < 115 m per ~~Ma~~Myr from mid-Carboniferous to mid-Permian times (325–265 Ma), suggest a transition from extensive, widespread Caledonian thrusting and collapse-related normal faulting to milder normal faulting in the late Carboniferous–mid Permian. The high number of early–mid Permian, K~~/~~–Ar ages may, alternatively, reflect an episode of (near-) surface weathering in NW Finnmark. Subsequent Mesozoic–Cenozoic extension migrated westwards and NW Finnmark remained tectonically quiet from the mid-Permian.

Data availability

Structural field measurements, analyzed thin sections and K~~/~~–Ar geochronological data may be obtained from the corresponding author.

Author contribution

Jean-Baptiste P. Koehl acquired field measurements and fault-rock samples with the help of Prof. Steffen Bergh. K~~/~~–Ar analyses were performed by Prof- Klaus Wemmer at the University of Göttingen and interpreted by Jean-Baptiste P. Koehl and Prof. Wemmer. The writing part was mostly done by Jean-Baptiste Koehl with the help of Prof. Bergh. Contributions as follow: Jean-Baptiste P. Koehl (40 %), Prof. Steffen Bergh (30 %) and Prof. Klaus Wemmer (30 %).

Competing interests

The authors declare that they have no conflict of interest.

Acknowledgements

The present study is part of the ARCEx project (Research Centre for Arctic Petroleum Exploration), which is funded by the Research Council of Norway (grant number 228107) together with ten academic and eight industry partners. We would like to thank all the persons from these institutions that are involved in this project. We acknowledge the contribution of student research assistants from the K/–Ar laboratory at the University of Göttingen for their work preparing and analyzing the samples of non-cohesive fault-rock presented in this study. Finally, the authors would like to thank Anna Ksienzyk from the University of Bergen for fruitful discussions.

Figure 2: Outcrop photographs of the dated faults. Each photograph is accompanied of the location of the dated samples (yellow squares; see Figure 1 for sample location), structural measurements presented in white boxes and in Schmidt stereonets (left hand-side stereonets show fracture surfaces as great circles and right hand-side stereonets display slickenside lineations as pole to fault surfaces indicating the movement of the hanging- wall), and potential kinematic indicators where available. (a) ENE-WSW-trending, NWNNW-dipping Altafjorden fault 1 (sample 3) crosscuttingcross-cutting Precambrian rocks of the Alta–Kvænangen tectonic window along the western shore of Altafjorden. A potentially drag-folded mafic bed is shown in blue. Modified after Koehl et al (submitted); (b) ENE-WSW-trending, NWNNW-dipping Altafjorden fault 2 (sample 4) within the Alta–Kvænangen tectonic window. The country-rock displays preserved bedding surfaces (in dotted yellow); (c) ENE-WSW-trending, NWNNW-dipping fault in the footwall of the Sørkjosen fault (Sørkjosen 1; sample 1). A potentially offset mafic bed is shown in green and the bedrock fabric in dotted orange. The lower left frame is a zoom in the fault-core displaying the location of the dated sample; (d) ENE-WSW-trending, NWNNW-dipping fault in the footwall of the Sørkjosen fault (Sørkjosen 2; sample 2). Dotted yellow lines show normal offsets of mafic beds across brittle faults; (e) E-W-trending, NNorth-dipping Talvik fault (sample 5) crosscuttingcross-cutting rocks of the Kalak Nappe Complex along the western shore of Altafjorden. Kinematic indicators include ductile fabrics made of microshears (lower left frame), sigma-clasts (middle left frame) and slickenside lineations (upper right frame). The bedrock fabric is shown in green. Modified after Koehl et al (submitted); (f) NNE–SSW-trending-striking brittle faults crosscuttingcross-cutting rocks of the Kalak Nappe Complex along the eastern shore of Altafjorden (sample 6). See normal offsets of geological markers (in green and blue). Modified after Koehl et al (submitted); (g) NE-SW-trending, SE-dipping fault segment of the Snøfjorden–Slatten fault (sample 7) in Snøfjorden, on the Porsanger Peninsula. Modified after Koehl et al (submitted); (h) Low-angle, WNW-ESE-trending, NE, NNE-dipping fault (sample 8) crosscuttingcross-cutting rocks of the Kalak Nappe Complex on the Porsanger Peninsula; (i) Steep, E–W- to WNW–ESE-trending-striking faults (sample 9) within the gabbroic rocks of the Honningsvåg Igneous Complex; (j) Steep, WNW–ESE-trending-striking brittle faults near Gjesvær (sample 10), in the western part of Magerøya. The faults crosscuscross-cut rocks of the Kalak Nappe Complex.

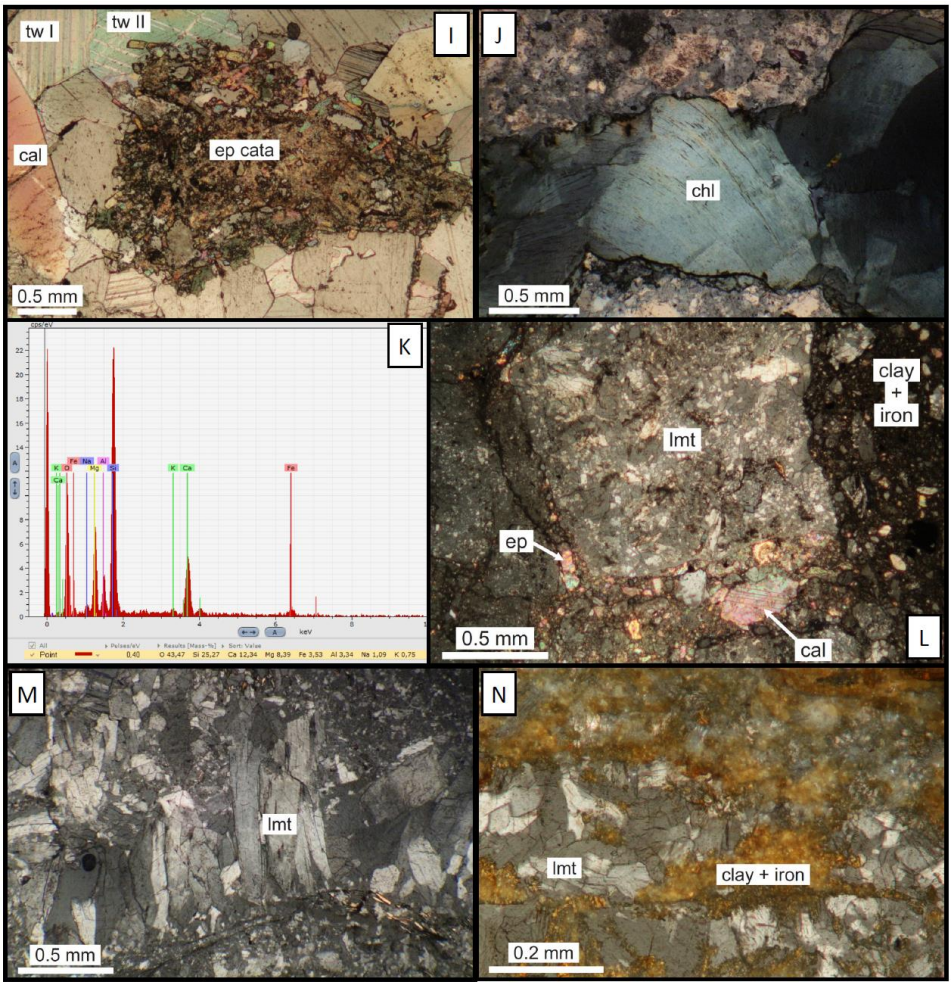

Figure 3: Microscope photographs of cataclasite and ~~hostrock~~host-rock in NW Finnmark. (a) Precambrian S-C foliation made of muscovite (ms) microcrystals surrounding K-feldspar (Kfs) sigma-clasts. Location at faults 3 and 4 (Figure 1); (b) Cataclasite vein (dashed green) in Precambrian basement rocks seemingly offset by iron- and clay-rich fractures that formed parallel to existing S-C foliation deformation planes (dotted pink). The amount of offset across iron-rich fractures is shown by a dextrally (red) offset, sheared quartz grain (yellow) and is lower than the apparent offset of the cataclastic vein in green. Location at faults 3 and 4 (Figure 1); (c) Calcite-filled (cal) fracturein Precambrian basement rocks ~~crosscutting~~cross-cutting a vein of recrystallized quartz (qz) and a muscovite-bearing (ms) ductile microshear. Calcite cement crystals typically show type II (tw II; lower right inset) and type IV (tw IV; upper left inset) twinnings. Location at faults 3 and 4 (Figure 1); (d) Preserved biotite (bt) foliation in Caledonian host rocks near a cataclastic (cata) brittle fault. Approaching the fault, biotite is increasingly recrystallized into chlorite (chl). Location at fault 7 (Figure 1); (e) Highly fractured garnet crystal (grt) in Caledonian host rock ~~crosscut~~cross-cut by epidote- (ep; type 1) and quartz-rich cataclasites (qz cata; type 2), which are both truncated by calcite-filled veins (cal; type 3). Both cataclasites and calcite veins are truncated by a third cataclasite made up with a matrix of angular, poorly sorted clasts of laumontite (lmt; type 4) ~~crosscut~~cross-cut by late clay and iron-bearing veins (type 5). Location at the Langfjorden fault segment of the LVF (Koehl et al., submitted), ca. 10–15 km west of

the Talvik fault (fault 5 in Figure 1); (f) Caledonian S-C foliation made of muscovite (ms) microcrystals surrounding K-feldspar (Kfs) sigma-clasts that have partly recrystallized into quartz (qz). Location at faults 1 and 2 (Figure 1); (g) Cataclastic fault-rock showing the remains of ~~pre-existing~~preexisting S, C and C' foliation deformation planes in dotted yellow along which brittle fractures formed. Location ca. 10–15 km south-southeast of fault 7 (Figure 1); (h) Epidote-rich cataclasite (ep cata; type 1) in Caledonian host rock including clasts of stilpnomelane (stp) ~~crosscutting~~cross-cutting quartz-rich host rock (qz) and truncated by quartz-rich cataclasite (qz cata; type 2), which incorporates clasts of epidte-rich cataclasite (yellow; type 1). ~~Ep~~Epidote- (type 1) and quartz-rich (type 2) cataclasites are truncated by subsequent clay and iron-rich veins (type 5). Location at fault 9 (Figure 1); (i) Epidote-rich cataclasite (ep cata; type 1) embedded within a calcitic cement (cal; type 3) made of large crystals showing type I (tw I) and type II (tw II) twinnings. Location at the Straumfjordbotn fault (Koehl et al., submitted, their figure 6g), a few km east of faults 1 and 2 (Figure 1); (j) Fracture with chlorite (chl) precipitation related with type 1 cataclasite. Location at fault 7 (Figure 1); (k) SEM analysis of the atomic composition of the stilpnomelane crystal shown in type 1 cataclasite in (h). The numbers below the graph represent mass percentage of each atom; (l) Large clasts of laumontite-rich (lmt; type 4) cataclasite ~~crosscut~~cross-cut at the bottom of the photograph by a cataclastic vein including clasts of epidote (ep; type 1), quartz (type 2), calcite (cal; type 3) and laumontite (type 4), and on the right hand-side by a cataclastic vein containing mostly iron-bearing and clay minerals (type 5). The iron- and clay-rich cataclasite (type 5) truncates all the other types of cataclasites. Location as (e); (m) Laumontite precipitations (lmt; type 4 cataclasite). Crystals are elongated perpendicular to the fracture along which they precipitated. Location 4–5 km west-northwest of fault 9 (Figure 1; also see Koehl et al., submitted, their figure 12c); (n) Iron- and clay-rich (type 5) cataclasite ~~crosscutting~~cross-cutting mildly fractured late growth of laumontite (lmt; type 4). Location at the Øksfjorden fault, in Øksfjorden (Koehl et al., submitted, their figure 7b), ca. 25 km west-northwest of fault 5 (Figure 1).

Table 1: Mineral composition of dated fault gouges. "Presumed traces" are based on inclined spectra (~~cf.~~ Appendix A) showing peaks at 27.3–27.4 for K-feldspar, and on the presence of minor illite in smectite, enabling K/Ar dating, e.g. samples 9 and 10. Abbreviations: chl = chlorite; I = illite; kao = kaolinite; Kfs = K-feldspar; lmt = laumontite; Qz = quartz; S = smectite.

	5447	1,48	16,23	94,71	**312,5**	8,7	2,8

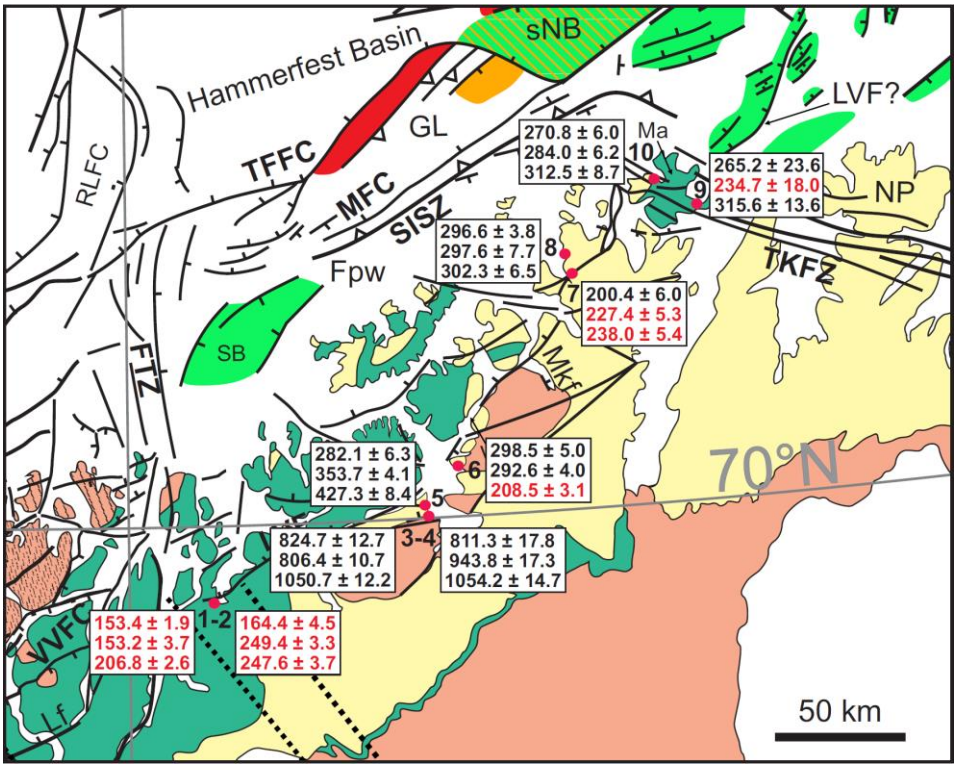

Figure 4: Structural map of the study area showing the obtained K/–Ar ages for each sample in Ma, including from top to bottom finest, intermediate and coarsest grainsize fraction ages. Ages in red are considered erroneous (~~cf.~~see main text). Map modified after Indrevær et al., (2013) and Koehl et al. (2018). Legend and abbreviations as in Figure 1~~Figure 1~~.

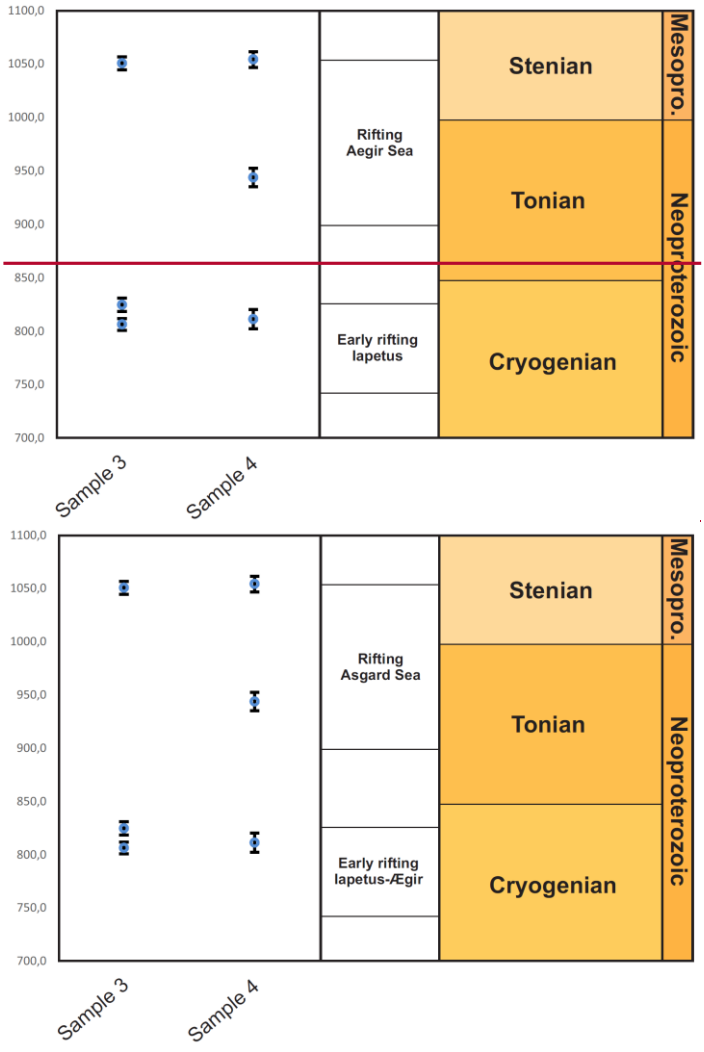

Figure 5: Graph displaying the obtained Precambrian ages for brittle faults in the Alta–Kvænangen tectonic window. The vertical axis is time in Ma and the horizontal axis shows the dated sample numbers, which locations are displayed in Figure 1~~Figure 1~~ &and Figure 4~~Figure 4~~. Columns to the right show extensional tectonic events related to the formation of the NW Baltoscandian basins during the opening of the Asgard Sea (Siedlecka et al., 2004; Nystuen et al., 2008; Cawood et al., 2010; Cawood &and Pisarevsky, 2017) and to the earliest phase of rifting of the Iapetus Ocean–Ægir Sea (Li et al., 1999, 2008; Torsvik &and Rehnström, 2001; Hartz &and Torsvik, 2002), and associated geological Periods and Eras.

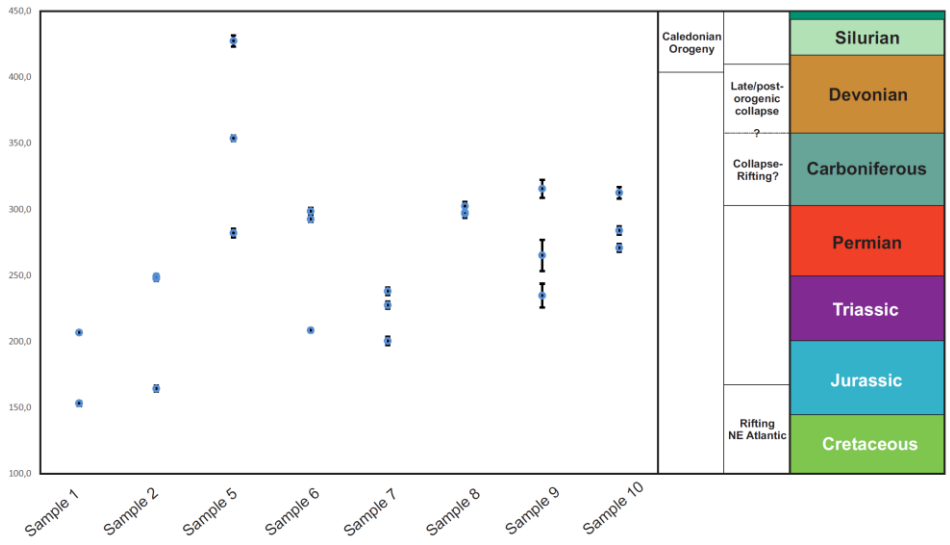

Figure 6: Graph showing the Phanerozoic K/–Ar ages and associated error obtained for fault gouge samples in NW Finnmark. The vertical axis represents time in Ma and the horizontal axis shows the dated sample numbers, which locations are displayed in Figure 1~~Figure 1~~ &~~,~~and Figure 4~~Figure 4~~. Columns to the right of the graph display major contractional (based on Ramberg et al., 2008; Vetti, 2008; Corfu et al., 2014) and extensional events (Faleide et al., 1993; Steltenpohl et al., 2011; Koehl et al., 2018) that affected North Norway in late Paleozoic–Mesozoic times, and associated geological time Periods.

Appendix A: X-Ray Diffraction spectrum of copper graphs showing the mineralogical composition of the dated fault-rock samples. Green, blue and red lines respectively represent coarse, intermediate and fine grainsize fractions for each sample. Abbreviations: chl = chlorite; ill = illite; Kfs = K-feldspar; lmt = laumontite; qz = quartz; sme = smectite.
