## Abstract

This paper presents an alternative approach for estimating the Biot coefficient for the Grimsel granite, which appeals to the multi-phasic mineralogical composition of the rock. The modelling considers the transversely isotropic nature of the rock that is evident from both the visual appearance of the rock and determined from mechanical testing. Conventionally, estimation of the compressibility of the solid material is performed by fluid saturation of the pore space and pressurization. The drawback of this approach in terms of complicated experimentation and influences of the unsaturated pore space is alleviated by adopting the methods for estimating the solid material compressibility using developments in theories of multiphase materials. The results of the proposed approach are compared with estimates available in the literature.

*Keywords:* Biot coefficient, transversely isotropic rocks, compressibility of the solid materials, Walpole bounds, Voigt-Reuss-Hill estimates

---

## 1. Introduction

The classical theory of poroelasticity proposed by Biot (1941) is a major contribution to the disciplines of geosciences and geomechanics with applications that include porous earth materials saturated by fluids. The studies in this area are numerous and no attempt will be made to provide a comprehensive survey of past and recent developments. Advances in the area of poroelasticity, and its applications to problems in geomechanics in particular are given by Rice and Cleary (1976); Yue and Selvadurai (1995); Selvadurai (1996, 2007); Wang (2000); Verruijt (2015); Cheng (2015); Selvadurai et al. (2015); Selvadurai and Suvorov (2016) and others. The basic development of the classical theory of poroelasticity relies on constitutive assumptions of Hookean elastic behaviour of the porous skeleton and Darcy flow through the porous medium. In addition, an important component of the theory relates to the partitioning of the total stress tensor for the poroelastic solid between the stresses carried purely by the porous skeleton and the stresses carried by the pore fluid. The partitioning is an important component in the theory of poroelasticity that allows the time-dependent shedding of the applied stresses from the pore fluid to the porous skeleton. The stresses sustained by the porous skeleton have important consequences to the definition of failure of the poroelastic material either through the development of damage (Selvadurai, 2004; Selvadurai and Shirazi, 2004, 2005; Selvadurai et al., 2015), or fracture development and boundary effects on heterogeneities (Selvadurai et al., 2011; Selvadurai and Głowacki, 2017, 2018)

24 or plastic flow (Selvadurai and Suvorov, 2012, 2014). From an environmental geosciences perspective, alterations in  
25 the skeletal permeability associated with its damage can lead to enhanced migration of contaminants and hazardous  
26 materials. In Biot's theory, the partitioning of the total stress is achieved through consideration of the bulk modulus  
27 of the porous skeleton ( $K_D$ ) and the bulk modulus of the solid material composing the porous skeleton ( $K_S$ ), which  
28 introduces the Biot coefficient  $\alpha$  and for an isotropic elastic skeleton, has the form  $\alpha = 1 - (K_D/K_S)$ . When the bulk  
29 modulus of solid material is large in comparison to the skeletal bulk modulus,  $\alpha \rightarrow 0$ , which is the conventional stress  
30 partitioning approach proposed in the theory of soil consolidation proposed by Terzaghi (1923). Unlike in soils, the  
31 Biot coefficient for rocks can be less than unity. If Biot's classical theory of poroelasticity is accepted, values of  $\alpha$   
32 cannot be greater than unity. Such a value would imply that either  $K_D < 0$  or  $K_S < 0$ , which would violate the positive  
33 definiteness arguments for the strain energy of an elastic porous skeleton (Davis and Selvadurai, 1996; Selvadurai,  
34 2000) with no locked-in self equilibrating stresses (i.e. the skeleton expands under compressive isotropic stresses). It  
35 should also be noted that the Biot coefficient as originally envisaged by Biot (1941) is a scalar parameter. Extension  
36 of the theory to consider an anisotropic skeletal fabric is admissible but the coefficient still remains a scalar parameter.  
37 A range of values for  $\alpha$  is given by Detournay and Cheng (1993); Wang (2000); Cheng (2015).

38 The experimental procedure for determining the Biot coefficient  $\alpha$  involves estimating the bulk modulus of the  
39 porous skeleton ( $K_D$ ), which, in the case of an isotropic skeletal fabric, can be obtained by subjecting a dry or mois-  
40 ture free and jacketed specimen of the rock to isotropic compression and measuring the resulting volumetric strain.  
41 This is a straightforward experimental technique and the results can also be verified by conducting uniaxial compres-  
42 sion tests on the isotropic rock and measuring both the Young's modulus and Poisson's ratio. The measurement of  
43 the compressibility of the solid material composing the skeletal fabric can be either straightforward or complicated  
44 depending on the permeability characteristics of the porous material. For rocks with relatively high permeability (e.g.  
45 Indiana limestone  $10^{-13} \sim 10^{-15} \text{m}^2$  (Selvadurai and Glowacki, 2008; Selvadurai and Selvadurai, 2010, 2014), Vosges  
46 sandstone  $\sim 10^{-13} \text{m}^2$  (Moulu et al., 1997), etc.), the pore space of the rock can be saturated by initiating a combination  
47 of steady flow and vacuum saturation. To determine the compressibility of the solid material, the confining isotropic  
48 stresses are allowed to nearly equilibrate with the pore fluid pressure and the volume changes measured can be used  
49 to estimate the compressibility of the solid material composing the porous fabric.

50 The ideal arrangement for the measurement of the  $K_S$  would involve an unjacketed specimen where the saturating  
51 fluid is identical to the pressurizing fluid. In situations where the saturating fluid is water and the pressurizing fluid  
52 is oil (needed to attain high pressures without compressibility issues), the sample needs to be jacketed. The sample  
53 can be subjected to a constant high confining pressure and the pore fluid pressure increased to attain equilibrium.  
54 This appears to be the preferred mode of estimation of the solid material compressibility provided the saturation of  
55 the pore space is assured within the timeframe of a test. Other variations on this procedure are possible depending  
56 on the permeability of the rock under investigation. The article by Bemmer et al. (2004) relating to the measurement  
57 of poroelastic parameters for the Meuse/Haute Marne argillites advocates the use of oedometric compression tests  
58 for the estimation of the Biot coefficient. If ever there is a criticism in the use of oedometric compression tests for  
59 estimating the Biot coefficient, this relates to the radial stress developed in the sample, which is a function of the  
60 skeletal Poisson's ratio, which adds a level of uncertainty in the interpretation of the solid material compressibility.  
61 Also, the Meuse/Haute Marne argillite is a clay rock, which will have irreversible deformations in terms of the stress  
62 history and the interpretation of the skeletal elasticity properties should reflect stress history. In the case of the Grimsel  
63 granite, such effects are not expected to be significant.

64 With very low permeability materials (e.g. the Cobourg limestone  $\sim 10^{-23} \text{m}^2$  to  $10^{-19} \text{m}^2$  (Selvadurai et al., 2011)),

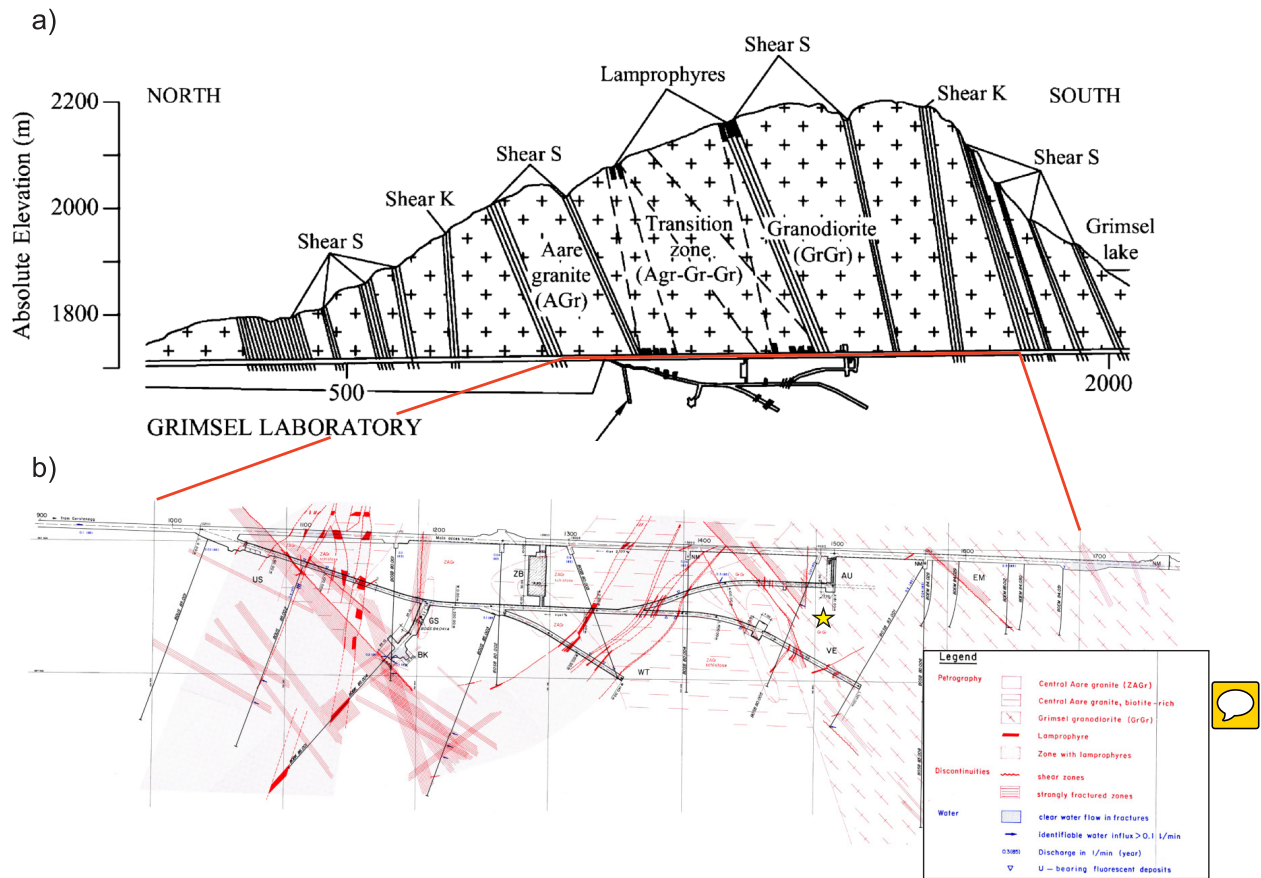

Figure 1: (a) The Grimsel Laboratory and the FEBEX Drift [After Alonso et al. (2005)]; (b) Detailed map view of the FEBEX drift for reference only [After Keusen et al. (1989) and from NAGRA Technical Report NTB87-14E].

65 the process of saturation of the pore space can take an inordinately long time with no assurance that the entire pore  
 66 space is fully saturated or that there are no residual pore fluid pressure artifacts (Selvadurai, 2009). Furthermore,  
 67 even if the pore space is saturated, attaining equalization of the externally applied pressure with the internal pore fluid  
 68 pressure can take substantial time (for 150 mm diameter cylindrical Cobourg limestone samples, more than 100 days  
 69 are required for saturation). For this reason, ? proposed an alternative approach where the compressibility of the solid  
 70 material phase(s) can be estimated by considering the multi-phasic theories developed for estimating the effective  
 71 properties of composite elastic materials. The composite material theories associated with the Voigt-Reuss-Hill esti-  
 72 mates (Voigt, 1928; Reuss, 1929; Hill, 1952, 1965) and the upper and lower bound estimates proposed by Hashin and  
 73 Shtrikman (1963) can be used to estimate the bulk modulus of the solid material (see also Walpole, 1966; Francfort  
 74 and Murat, 1986). In this paper, we apply these basic concepts to determine the Biot coefficient for the Grimsel gran-  
 75 ite. This granite is encountered in the Underground Research Laboratory constructed in Grimsel, Switzerland, in order  
 76 to perform heater experiments to simulate the thermo-hydro-mechanical (THM) loading associated with heat-emitting  
 77 containers in the event that the site is chosen as a repository for the deep geologic disposal of high level nuclear fuel  
 78 waste (i.e. the Full-scale Engineered Barriers EXperiment (FEBEX).) A typical section along the Grimsel Laboratory  
 79 associated with the FEBEX heater experiment location is shown in Figure 1.

80 The Aar granitic rock (also referred to as Aare granitic rock) setting at Grimsel has been associated with initiatives  
81 related to the use of granitic rock formations as potential hosts for the creation of deep geologic repositories for the  
82 disposal of heat-emitting nuclear fuel waste. Detailed descriptions of the geological settings of the Aar massif of  
83 the Central Alps are given by several authors including Stalder (1964); Wüthrich (1965); Steck (1968); Schaltegger  
84 (1990b,a); Schaltegger and Corfu (1992) and references to further studies are given by Goncalves et al. (2012). Geo-  
85 scientific studies of the Aar granite have been conducted by a number of agencies including NAGRA and ENRESA  
86 and these initiatives are documented in several reports and articles by Amiguet (1985); Pahl et al. (1989); Keusen et al.  
87 (1989); Möri et al. (2003); Alonso and Alcoverro (2005); Alonso et al. (2005); Rabung et al. (2012); Bouffier (2015);  
88 Garralón et al. (2017); Krietsch et al. (2019). In relation to the FEBEX research experiments, the geological setting  
89 of the Grimsel Laboratory contains alternate layers of the Aar granite, transition zones and Granodiorite, separated  
90 by Lamprophyres and zones that are subjected to intense shearing. A typical view of the geological setting is shown  
91 in Figure 1. During the FEBEX experiments, the Grimsel Laboratory was used to conduct heater experiments where  
92 the heaters were encapsulated in bentonitic clay. An extensive program of research was conducted by a series of  
93 research groups to validate the THM response of both the bentonitic buffer and the rock mass and the results of the  
94 research efforts are documented by Alonso and Alcoverro (2005) and Alonso et al. (2005). The Grimsel granite used  
95 in this research investigation was obtained from boreholes PRP16.001 and INJ16.001 located in the southern part of  
96 the laboratory, drilled from the AU cavern. These boreholes were drilled as a part of the Grimsel In-situ Stimulation  
97 and Circulation (ISC) project (see the location in Figure 1) that investigated the seismo-hydro-mechanical response  
98 of the rock mass to hydraulic stimulation (Amann et al., 2018; Gischig et al., 2018; Doetsch et al., 2018; Jalali et al.,  
99 2018).

100 During the geological evolution of the Aar Massif, the strata acquired different mineralogical compositions and  
101 the studies by Schaltegger and Krähenbühl (1990) contain very detailed evaluations of the mineralogical composi-  
102 tions of rocks recovered from the Grimsel and Reuss regions. This information is valuable for estimating the solid  
103 material compressibility of the Grimsel granite and for distinguishing the sample locations. For example, the work of  
104 Jokelainen et al. (2013) provides information on the mineralogical composition of the Grimsel granodiorite and the  
105 study by Missana and Garcia-Gutiérrez (2012) provides the mineralogical composition of the FEBEX granite. The  
106 results reported in these investigations are summarized in Tables 1-4 for completeness.

107 Figure 2 shows cores of the Grimsel granite and, from a visual perspective, the rock has the appearance of strati-  
108 fications that would point to the likely presence of transverse isotropy, in terms of its elasticity properties, fluid flow  
109 and fracture and failure characteristics.

110 The microstructure includes larger crystals of quartz (with dimensions up to 8 mm) and this requires that a suitable  
111 representative volume element is considered, both in the mechanical testing and mineralogical property evaluations.  
112 Extensive geomechanical characterization studies have been performed on the Grimsel granite and these are given  
113 in the references cited previously. Permeability studies are also reported by Schild et al. (2001). A comprehensive  
114 inter-laboratory study of permeability of the Grimsel granodiorite is also given in David et al. (2018a,b).

115 The objective of this study is to employ the existing data on the mechanical characterization of the transversely  
116 isotropic granite to estimate the skeletal compressibility of the granite and to use XRD studies of the mineralogical  
117 composition of the Grimsel granite to estimate the compressibility of the solid phase composing the porous fabric.

Table 1: Short Petrographical Descriptions of the Rock Samples Analyzed by Schaltegger and Krähenbühl (1990). Compositions are estimated from thin section, all=allanite; ap=apatite; bio=biotite; cc=calcite; chl=chlorite; ep=epidote; fluo=fluorite; gar=garnet; kfs=K-feldspar; leuc=leucoxene; op=opaques; plag=plagioclase; ser=sericite; sph=sphene; stilp = stilpnomelane; qtz = quartz; zir = zircon.

## 2. Skeletal Bulk Modulus of the Grimsel Granite

The fabric of the Grimsel granite is indicative of a transversely isotropic material (Nejati, 2018; Dutler et al., 2018; Dambly et al., 2019; Nejati et al., 2019). The elastic stress-strain relationships for a transversely isotropic material can be expressed in several forms (see e.g. Hearmon, 1961; Lekhnitskii, 1963; Ting, 1996). We consider the case where the plane of isotropy ( $x, y$ ) of the transversely isotropic elastic material is normal to the  $z$ -axis. The equations of elasticity governing the normal strains can be written in the forms

$$\begin{aligned}
 \epsilon_{xx} &= \frac{\sigma_{xx}}{E_x} - \frac{\nu_{yx}\sigma_{yy}}{E_y} - \frac{\nu_{zx}\sigma_{zz}}{E_z} \\
 \epsilon_{yy} &= -\frac{\nu_{xy}\sigma_{xx}}{E_x} + \frac{\sigma_{yy}}{E_y} - \frac{\nu_{zy}\sigma_{zz}}{E_z} \\
 \epsilon_{zz} &= -\frac{\nu_{xz}\sigma_{xx}}{E_x} - \frac{\nu_{yz}\sigma_{yy}}{E_y} + \frac{\sigma_{zz}}{E_z}
 \end{aligned} \tag{1}$$

We point out that the Poisson's ratio is generally defined as  $\nu_{ij} = -\epsilon_j/\epsilon_i$  for a stress in the  $i$  direction. From Betti's reciprocal theorem,

Table 2: Geochemical Descriptions of the Rock Samples Across the Grimsel Test Site given by Keusen et al. (1989).

Table 3: Mineralogical composition of the Grimsel Granodiorite (Gr-Gr) [After Jokelainen et al. (2013)].

| Mineral              | Sample 1 (Volume %) | Sample 2 (Volume %) |
|----------------------|---------------------|---------------------|
| Plagioclase          | 39.0                | 34.0                |
| Quartz               | 28.4                | 37.2                |
| K-Feldspar           | 21.6                | 12.8                |
| Biotite              | 5.0                 | 7.8                 |
| Muscovite + sericite | 2.6                 | 1.6                 |
| Epidote              | 1.2                 | 1.0                 |
| Amphibole            | 1.8                 | 4.6                 |
| Chlorite             | 0.2                 | 0.4                 |
| Titanate             | -                   | 0.6                 |
| Opaque minerals      | 0.2                 | -                   |

$$\frac{\nu_{xy}}{E_x} = \frac{\nu_{yx}}{E_y}, \quad \frac{\nu_{xz}}{E_x} = \frac{\nu_{zx}}{E_z}, \quad \frac{\nu_{yz}}{E_y} = \frac{\nu_{zy}}{E_z} \quad (2)$$

126 Due to the isotropic behaviour in the  $xy$  plane,  $E_x = E_y$ , and  $\nu_{xy} = \nu_{yx}$ . These relations reduce the independent  
 127 material constants needed to define the principal strains to four:  $E_x$ ,  $E_z$ ,  $\nu_{xy}$  and  $\nu_{zx}$ . Consider the situation where an  
 128 element of the transversely isotropic elastic medium is subjected to an isotropic compressive stress state:  $\sigma_{xx} = \sigma_{yy} =$   
 129  $\sigma_{zz} = p$ . The infinitesimal volumetric strain

$$\epsilon_v = \epsilon_{xx} + \epsilon_{yy} + \epsilon_{zz} = p \left[ \frac{2}{E_x} (1 - \nu_{xy}) + \frac{1}{E_z} (1 - 4\nu_{zx}) \right] \quad (3)$$

130 The skeletal bulk modulus for the transversely isotropic elastic material can be expressed in the form

$$K_D^{\text{TI}} = \frac{p}{\epsilon_v} = \frac{E_x E_z}{2E_z(1 - \nu_{xy}) + E_x(1 - 4\nu_{zx})} \quad (4)$$

131 In terms of the elasticity parameters that are applicable to the direction normal to the planes of stratification ( $N$ )  
 132 and directions along the planes of foliation or stratification ( $T$ ), Eq. (4) can be written as

$$K_D^{\text{TI}} = \frac{E_T E_N}{2E_N(1 - \nu_{TT}) + E_T(1 - 4\nu_{NT})} \quad (5)$$

133 In the limit of material isotropy,  $E_N = E_T = E$  and  $\nu_{TT} = \nu_{NT} = \nu$  and Eq. (5) reduces to the classical result

Table 4: Mineralogical composition of the FEBEX Granite [After Missana and Garcia-Gutiérrez (2012)].

| Mineral            | Volume (%) |
|--------------------|------------|
| Quartz             | 30-36      |
| Plagioclase/Albite | 19-23      |
| K-Feldspar         | 31-37      |
| Biotite-Chlorite   | 6-8        |
| Muscovite          | 1-2        |

Figure 2: The Grimsel granite sample taken from the PRP1 borehole, with a diameter of 110 mm and a length of 240 mm. The nominal planes of stratification are inclined at about 50° to the axis of the sample.

$$K_D^I = \frac{E}{3(1 - 2\nu)} \quad (6)$$

134 The estimation of the skeletal bulk modulus of the Grimsel granite can be attempted provided that the elasticity  
 135 constants applicable to either an isotropic fabric or a transversely isotropic skeletal elastic behaviour, can be identified.  
 136 The geomechanical investigations of the granitic rocks at Grimsel have ranged from the estimation of the deformability  
 137 and strength characteristics of the rock to the assessment of the in situ stress state. The interpretation of the available  
 138 data for estimating the *skeletal deformability characteristics* is complicated by the fact that the approaches used are  
 139 not uniform and standardized; the earlier experimental studies may have deviated from currently acceptable standards  
 140 (as suggested by ASTM and ISRM) for sample size, rate of loading, end restraints, method of interpretation of  
 141 the experimental data for parameter extraction (secant modulus, tangent modulus, loading/unloading paths, cycles),  
 142 etc. The exercise is also compounded by the material variability in terms of the Grimsel lithology and its influence  
 143 on parameter variability. Within these limitations, attempts can be made to extract, from the existing literature,  
 144 representative values of the elasticity characteristics of Grimsel granite with due consideration for the species of  
 145 granite. The earliest record used in this study relates to the work of Amiguet (1985) and Alonso and Alcoverro  
 146 (2005), which indicate the elasticity properties as  $E \approx 60$  GPa;  $\nu \approx 0.25$ .

147 Pahl et al. (1989) used borehole dilatometer and overcoring to estimate the in-situ stress state and the overall  
 148 deformability characteristics of the granite:  $E \approx 40$  GPa;  $\nu \approx 0.25$ . The work of Keusen et al. (1989) gives a range  
 149 of elasticity values applicable to the granodiorite ( $max[E \approx 63$  GPa;  $\nu \approx 0.48$ ];  $min[E \approx 32$  GPa;  $\nu \approx 0.18$ ]) and  
 150 the Aar granite ( $max[E \approx 64$  GPa;  $\nu \approx 0.49$ ];  $min[E \approx 42$  GPa;  $\nu \approx 0.25$ ]). Ziegler and Amann (2012) also report  
 151 the results of an extensive series of tests conducted on both wet and dry and coarse-grained and fine-grained samples  
 152 of Grimsel granite. The results are presented as maximum and minimum values as follows: for the coarse-grained  
 153 granite,  $max[E \approx 59$  GPa;  $\nu \approx 0.37$ ];  $min[E \approx 53$  GPa;  $\nu \approx 0.25$ ]; for the medium-grained granite. The recent work

154 of Bouffier (2015) uses laboratory over coring techniques to estimate the deformability characteristics of the Grimsel  
155 granite and there is a wide range of results for both the elastic modulus and Poisson's ratio; average representative  
156 results are indicated by  $E \approx 25$  GPa;  $\nu \approx 0.33$ . The work of Kant et al. (2017) is primarily focused on the estimation  
157 of the thermal properties of the Aar granite. The results they cite for the modulus of elasticity and Poisson's ratio are  
158 directly obtained from the work of Alonso et al. (2005) or indirectly from Keusen et al. (1989). Wenning et al. (2018)  
159 report studies of permeability and seismic velocity anisotropy across a ductile to brittle transition zone in the Grimsel  
160 granite.

161 The skeletal compressibility is also an important parameter in the interpretation of transient hydraulic pulse tests  
162 for estimating the fluid transport properties of low permeability materials including granite and argillaceous limestones  
163 (Brace et al., 1968; Selvadurai and Carnaffan, 1997; Selvadurai and Selvadurai, 2014; Selvadurai and Najari, 2015).  
164 The elasticity properties were determined via dynamic measurements and the maximum and minimum values are as  
165 follows:  $max[E \approx 95$  GPa;  $\nu \approx 0.18]$ ;  $min[E \approx 65$  GPa;  $\nu \approx 0.15]$ . Considering the nature of the ductile to brittle  
166 transmission zone under investigation and the dynamic nature of the tests, these estimates are far in excess of those  
167 for the intact material that is tested statically. Furthermore, the bulk modulus estimated from the maximum values of  
168  $E$  and  $\nu$  is in the range of 50 GPa, which is lower than the bulk modulus of mono-mineralic albite but exceeds that of  
169 quartz. The study by Krietsch et al. (2019) deals with the characterization of the in situ stress state at the Grimsel test  
170 site, using a range of experiments including overcoring and hydraulic fracturing. The investigations were extended to  
171 include transverse isotropy of the rock mass.

172 The elasticity parameters were inferred through a computational back analysis of the overcoring technique; these  
173 authors also provide a comparison with the results obtained by Bouffier (2015). An averaging procedure gives max-  
174 imum estimates of the isotropic elasticity parameters as  $E \approx 26$  GPa;  $\nu \approx 0.33$ . The use of the Grimsel Laboratory  
175 facility for the FEBEX experiment (Alonso and Alcoverro, 2005) provided a useful International Benchmarking ex-  
176 ercise to validate THM modelling of clay buffer regions that could be used in high-level nuclear waste management  
177 endeavours. The international collaborative effort (Alonso et al., 2005) focused more on the behaviour of the clay bar-  
178 rier during heating from emplaced heaters and fluid influx from the Grimsel granite. In many of the research efforts  
179 for the FEBEX Project, the Grimsel granite served as a heat sink and the rock mechanics aspects perhaps received  
180 less emphasis (i.e. the modelling of the bentonitic clay under heating was considered to be the major objective of  
181 the research as opposed to the modelling of the Grimsel granite). Also, to enhance fluid influx, the Grimsel gallery  
182 was considered to be a fractured rock mass and modelling the Grimsel rock elasticity properties varied between the  
183 research groups participating in the FEBEX project, with very low estimates of the elasticity properties (Nguyen et al.,  
184 2005) to near intact rock properties derived from the original studies of Amiguet (1985) (see also Gens et al., 1998;  
185 Alonso and Alcoverro, 2005; Rutqvist et al., 2003; Dupray et al., 2013). For this reason, the elasticity properties of  
186 the Grimsel granite cited in the papers dealing with the FEBEX exercise are excluded from consideration.

187 The majority of the studies focusing on the evaluation of the deformability characteristics of the Grimsel granite  
188 deal with isotropic elastic modelling. The possible influences of either elastic anisotropy or elastic transverse isotropy  
189 were addressed in the earlier study by Pahl et al. (1989) in connection with the estimation of in situ stress states. In  
190 this particular study, there is no clear statement of the applicable value of the elasticity constants governing transverse  
191 isotropy of the Grimsel granite (the degree of anisotropy ( $E_T/E_N$ ) does not exceed 1.25) and the study culminates  
192 in the adoption of the isotropic elasticity properties that were indicated previously. The research by Nejati (2018)  
193 and Nejati et al. (2019) deals with the estimation of the deformability characteristics of the Grimsel granite based  
194 on the transversely isotropic elastic model with principal directions aligned in the stratification planes and normal to

195 the planes (Figure 2). These studies indicate that the Grimsel granite tested also exhibited significant anisotropy and  
 196 nonlinearity. In addition, due to nonlinear effects, the secant, tangent and average values of the Young's modulus can  
 197 depend on the stress level at which the value is estimated.

198 If a range of elastic behaviour can be clearly defined and if the elastic constants governing transverse isotropy can  
 199 be determined, then, as shown by Eq. (5), the bulk modulus applicable to the transversely isotropic material can be  
 200 evaluated objectively. The studies conducted by Nejati (2018) and Nejati et al. (2019) provide the following estimates  
 201 for the elastic constants governing the transversely isotropic elasticity model for the Grimsel granite:  $E_N \approx 30$  GPa;  
 202  $E_T \approx 47$  GPa;  $\nu_{TT} \approx 0.20$  GPa;  $\nu_{NT} \approx 0.10$  GPa, Finally, Krietsch et al. (2019) conducted a series of experiments on  
 203 the ISC core plugs, using overcoring and external pressurization of the hollow samples. These authors also give results  
 204 of uniaxial tests conducted on core plugs extracted either normal or parallel to the foliations (Figure 18 of their paper).  
 205 These results can be used to estimate the  $E_N$  and  $E_T$ . From the results presented by Krietsch et al. (2019), the relevant  
 206 elastic moduli can be summarized as follows:  $E_N \approx 13$  GPa;  $E_T \approx 35$  GPa. These investigations, however, cannot be  
 207 used to estimate the values of  $\nu_{TT}$  and  $\nu_{NT}$ . Dambly et al. (2019) presented the results of a research program geared to  
 208 estimate the transversely isotropic elasticity parameters from results of ultrasonic dynamic tests and static tests. Nejati  
 209 et al. (2019) compared the static and dynamic values of the elastic constants at zero-confinement, and concluded that  
 210 the dynamic moduli are significantly greater than the static ones. In this study we have not considered experimental  
 211 results derived from dynamic testing; therefore, for consistency, any results derived from dynamic testing of the  
 212 Grimsel granite have been excluded from further consideration. Considering the experimental evaluations available  
 213 in the literature, the elasticity parameters applicable to the Grimsel granite are summarized in Table 5.

Table 5: Elasticity Properties for the Grimsel Granite with the corresponding  $K_D^I$  or  $K_D^{II}$  values:  $K_D^I = E/3(1 - 2\nu)$ ,  $K_D^{II} = E_T E_N / [2E_N(1 - \nu_{TT}) + E_T(1 - 4\nu_{NT})]$ ;  $N$  signifies the direction normal to the planes of stratification and  $T$  signifies the directions along the planes of stratification.

### 214 3. Compressibility of the Solid Material Composing the Grimsel Granite Fabric

215 The skeletal material of the Grimsel granite consists of a variety of mineral phases including quartz, biotite,  
 216 anorthite, augite, microcline and traces of pyrite and magnetite. The composition of these minerals were determined  
 217 both at the XRD facilities at University of Montréal, QC, Canada and at the Department of Earth Sciences, Institute  
 218 of Geology, ETH, Zurich (Wenning et al., 2018). The estimated volume fractions and the values for the bulk moduli  
 219 and shear moduli are shown in Tables 6 and 7 respectively. The average volume fractions and the mineralogical  
 220 compositions tend to vary and the estimated values are, in general, considered to be approximate. The results of the

221 XRD evaluations do not provide sufficient accuracy to group the tested rocks into either the Grimsel granodiorite or  
 222 the FEBEX Grimsel categories. A very cursory comparison with the data provided in Tables 1 to 3 would suggest  
 223 that the mineralogical compositions provided by Wenning et al. (2018) and indicated in Table 6 correspond to the  
 224 Grimsel granodiorite and the results shown in Table 7 correspond to the FEBEX granite. For this reason, the XRD  
 225 data derived from both laboratory evaluations (ETH and McGill) are retained in the estimations of the solid material  
 226 compressibility  $K_S$ . Also, the void fraction ( $\ll 1\%$ ) is neglected in the calculations. The values for the bulk moduli  
 227 and shear moduli for the various minerals were obtained from published literature (Alexandrov et al., 1964; Anderson  
 228 and Nafe, 1965; Carmichael, 1990; Sisodia and Verma, 1990; Moos et al., 1997; Redfern and Angel, 1999; Schilling  
 229 et al., 2003; Zhu et al., 2007; Mavko et al., 2009; Lin, 2013).

Table 6: Mineralogical Fractions of the Grimsel Granite [Data obtained by Wenning et al. (2018), Institute of Geology, ETH, Zurich].

| Mineral                         | Specific Gravity | %            | $K_S$ (GPa) | $G_S$ (GPa) |
|---------------------------------|------------------|--------------|-------------|-------------|
| <b>Biotite &amp; Phlogopite</b> | 2.72             | 10           | 77          | 42          |
| <b>Muscovite</b>                | 2.70             | 5            | 61          | 41          |
| <b>Epidote</b>                  | 2.75             | 6            | 107         | 60          |
| <b>Albite</b>                   | 3.19             | 40           | 76          | 26          |
| <b>Feldspar</b>                 | 2.60             | 16           | 76          | 26          |
| <b>Quartz</b>                   | 2.72             | 23           | 38          | 45          |
|                                 |                  | $\Sigma$ 100 |             |             |

Table 7: Mineralogical Fractions of the Grimsel Granite [Data obtained by the Earth Sciences Laboratory, University of Montréal].

| Mineral           | Specific Gravity | %            | $K_S$ (GPa) | $G_S$ (GPa) |
|-------------------|------------------|--------------|-------------|-------------|
| <b>Quartz</b>     | 2.72             | 46           | 38          | 45          |
| <b>Biotite</b>    | 2.70             | 5            | 77          | 42          |
| <b>Anorthite</b>  | 2.75             | 37           | 68          | 38          |
| <b>Augite</b>     | 3.19             | 5            | 95          | 59          |
| <b>Microcline</b> | 2.60             | 7            | 52          | 36          |
|                   |                  | $\Sigma$ 100 |             |             |

230 In the multi-phasic approach, the objective is to determine the overall bulk modulus for the solid mineralogical  
 231 phase by considering the bulk moduli for the separate mineral constituents and their volume fractions. The most  
 232 widely used relationships are those by Voigt (1928) and Reuss (1929). The Voigt ( $^V$ ) and the Reuss ( $^R$ ) estimates are

$$\begin{aligned}
 (K_S)_I^V &= \sum_i^n V_i (K_S)_i, & (K_S)_I^R &= \left[ \sum_i^n \frac{V_i}{(K_S)_i} \right]^{-1} \\
 (G_S)_I^V &= \sum_i^n V_i (G_S)_i, & (G_S)_I^R &= \left[ \sum_i^n \frac{V_i}{(G_S)_i} \right]^{-1}
 \end{aligned} \tag{7}$$

$i = \text{Qtz, Biotite, Anorthite, Augite, Microcline, Voids}$   
 $I = \text{Data from Table 1 or Table 2}$

233 The results given in Hill (1952, 1965) are the mean of the Voigt and Reuss estimates. This basic approach can be  
 234 applied to estimate the effective bulk and shear moduli for the Grimsel granite: i.e.

$$\begin{aligned}
 (K_S)_I &= \frac{1}{2} \left[ (K_S)_I^V + (K_S)_I^R \right], & (G_S)_I &= \frac{1}{2} \left[ (G_S)_I^V + (G_S)_I^R \right]
 \end{aligned} \tag{8}$$

$I = \text{Data from Table 1 or Table 2}$

235 Using the mineralogical compositions obtained from XRD analyses given in Table 1, we have

$$(K_S)_1 = 65 \text{ GPa}, \quad (G_S)_1 = 33 \text{ GPa} \quad (9)$$

236 and using the mineralogical compositions obtained from XRD analyses given in Table 2, we have

$$(K_S)_2 = 52 \text{ GPa}, \quad (G_S)_2 = 48 \text{ GPa} \quad (10)$$

237 We consider the upper and lower bounds for a multi-phasic composite consisting of  $n$  phases developed by Walpole  
238 (1966). The effective bulk modulus  $K$  for the multi-phasic material can be written as

$$\left[ \sum_{i=1}^n \left( \frac{V_i}{K_l^* + K_i} \right) \right]^{-1} - K_l^* \leq K \leq \left[ \sum_{i=1}^n \left( \frac{V_i}{K_g^* + K_i} \right) \right]^{-1} - K_g^* \quad (11)$$

239 where

$$K_l^* = \frac{4}{3}G_l, \quad K_g^* = \frac{4}{3}G_g \quad (12)$$

240 In Eq. (12),  $G_l$  and  $G_g$  are, respectively, the lowest and greatest values of the shear modulus of the  $n$  phases. For  
241 completeness, we also record here the bounds for the effective shear modulus ( $G$ ) of the  $n$  phasic mixture, which can  
242 be written as

$$\left[ \sum_{i=1}^n \left( \frac{V_i}{G_l^* + G_i} \right) \right]^{-1} - G_l^* \leq G \leq \left[ \sum_{i=1}^n \left( \frac{V_i}{G_g^* + G_i} \right) \right]^{-1} - G_g^* \quad (13)$$

243 where

$$G_l^* = \frac{3}{2} \left( \frac{1}{G_l} + \frac{10}{9K_l + 8G_l} \right)^{-1}, \quad G_g^* = \frac{3}{2} \left( \frac{1}{G_g} + \frac{10}{9K_g + 8G_g} \right)^{-1} \quad (14)$$

244 and  $K_l$  and  $K_g$  are, respectively, the lowest and greatest values of the bulk modulus of the  $n$  phases.

245 Considering the multiphasic data set given in Tables 6 and 7, respectively

$$(K_S)_1 \in (64.6, 65.9) \text{ GPa}, \quad (K_S)_2 \in (52.1, 52.7) \text{ GPa} \quad (15)$$

246 Considering the range of solid material compressibilities obtained from the two laboratory investigations we can  
247 conclude that the lower ( $^L$ ) and upper ( $^U$ ) estimates for  $K_S$  are approximately

$$K_S^L \approx 52 \text{ GPa}, \quad K_S^U \approx 66 \text{ GPa} \quad (16)$$

248 The results for the skeltal compressibilities given in Table 5 can be combined with the range of solid material  
249 compressibilities to estimate the *upper* and *lower* limits of the Biot coefficient applicable to each estimate of  $K_D^I$  and  
250  $K_D^{II}$ . The relevant results are shown in Table 8.

#### 251 4. Discussion

252 In theories developed for estimating the elasticity of multi-phasic materials, the most extensive studies relate to  
253 two-component elastic materials. Theories, however, have also been developed by several researchers to include a

Table 8: Upper and lower limits for the Biot coefficient for the Grimsel Granite;  $\alpha_U = 1 - (K_D^I \text{ or } K_D^{II})/K_S^U$ ,  $\alpha_L = 1 - (K_D^I \text{ or } K_D^{II})/K_S^L$ ,  $K_S^L \approx 52$  GPa,  $K_S^U \approx 66$  GPa.

254 distribution of three elastic phases in the composite material. An early study in this area is by Cohen and Ishai (1967)  
 255 that considered the presence of a large voids content in the two-phase system. Several other developments have been  
 256 proposed in the literature references to studies are given by Selvadurai (2019) and the other references cited in the  
 257 introduction. The extension to three elastic phases was also presented in the studies by Talbot et al. (1995) and, more  
 258 recently, by Lin and Ju (2009).

259 Here we have used the theoretical estimates proposed by Vogt and Reuss and modified by Hill, and the bounds  
 260 proposed by Walpole to estimate the upper and lower bound values for the effective bulk moduli of the solid phase.  
 261 It is shown that the estimates proposed by Voigt-Reuss-Hill and those of Walpole yield practically the same values.  
 262 The results of the evaluations presented in the paper would suggest that the multiphase approach in conjunction  
 263 with XRD data provides a useful alternative to validating the conventional experimental approach for estimating the  
 264 solid material composing low permeability porous media. The skeletal bulk moduli for the Grimsel granite shows a  
 265 wide variation, indicative of variable lithology of the igneous rock formation. In this sense, it is prudent to assume  
 266 a set of limits for the choice of the Biot coefficient rather than to assign a specific value. Certain data obtained in  
 267 this study give rise to non-realistic values of the Biot coefficient, clearly arising from the estimation of the skeletal  
 268 compressibility.

269 As a guide, experimental results for the skeletal compressibility values that exceed the effective solid material  
 270 compressibility of the minerals with the largest volume fractions should be disregarded. Therefore these results can  
 271 be excluded without further comment. (i.e. Since the multi-phasic assessment of the compressibility of the solid  
 272 material has a lower limit of approximately  $K_S^L \approx 50$  GPa, plausible values of the Biot coefficient will be obtained  
 273 when  $K_D < K_S$ .) Also, excessively low values of  $K_D$  need to be re-examined before using the data to estimate the  
 274 Biot coefficient. Excessively low values can result from inaccurate estimation of the elastic modulus and Poisson's  
 275 ratio. Similarly, excessively high values of the skeletal stiffness can result from inaccurate estimates of the Poisson's  
 276 ratio of the rock. For example, if samples are loaded in the direction of the foliations or stratifications, micro-crack  
 277 or defect development during compression can give rise to lateral deformations that can be a result of void/crack  
 278 generation and not a result of material deformation. Considering the numerical values presented in Table 8, and the  
 279 above comments, several estimates for the Biot coefficients can be excluded from further discussion. The Table 9  
 280 summarizes the revised set of realistic experimental estimates for the Biot coefficient of the Grimsel granite, taking  
 281 into consideration the aforementioned caveats on the experimental results. 

Table 9: Reduced Data Set for the Upper and Lower Limits for the Biot coefficient for the Grimsel Granite.

| Reference                           | Elasticity Type        | $K_D^I$ or $K_D^{II}$     | $\alpha_L$ | $\alpha_U$ |

## 5. Conclusions

The accurate estimation of the skeletal deformability characteristics of a porous rock is an essential pre-requisite for the estimation of the Biot coefficient for a fluid-saturated poroelastic material. While the procedures for conducting the either uniaxial or triaxial tests for estimation the skeletal deformability characteristics is well known, the exact procedure for estimating the elastic moduli, Poisson's ratio, etc., needs to be better documented so that the interpretations of experimental data can be consistent. The conventional procedure for the pressurization of a saturated sample of the rock and the measurement of the resulting sample strains when the externally applied cell pressure matches the pore fluid pressure is perhaps the best procedure for estimating the compressibility of the solid phases of the porous medium. This, however, is not a routine procedure for low permeability materials and substantial pressures need to be applied to ensure that volumetric strains of an accurately measurable value can be recorded. Also, in such cases the strains could involve irreversible grain boundary frictional slip and this needs to be excluded from the estimation of the solid material compressibility.

Here, we advocate the use of a multiphasic approach where the theories of composite materials can be used to estimate the compressibility of the solid material composing the porous skeleton. This is a relatively easy approach since XRD evaluations of the mineralogical phase composition are usually carried out to characterize the rock. In relation to the Grimsel granite, the analysis points to a Biot coefficient that has bounds rather than a specific value: i.e.  $0.48 < \alpha < 0.71$ . Values for the Biot coefficient for other types of rocks include the following [see also Table 1 in Detournay and Cheng (1993)]: Westerly granite ( $\alpha \approx 0.47$ ). Values for the Biot coefficient for other types of granite in Manitoba, Canada, a value of  $\alpha = 0.73$  is cited (Lau and Chandler, 2004); Sandstones have also shown this same variability: Ruhr sandstone ( $\alpha \approx 0.65$ ), Berea sandstone ( $\alpha \approx 0.79$ ), Weber sandstone ( $\alpha \approx 0.64$ ), Ohio ( $\alpha \approx 0.65$ ), Pecos sandstone ( $\alpha \approx 0.83$ ) and Boise sandstone ( $\alpha \approx 0.85$ ) [Further estimates are provided by Zimmerman (1991)]; Cobourg limestone ( $\alpha \approx 0.66$ ). With soft rocks such as chalk, the Biot coefficient is invariably in the range 0.80 to 1.0 (Alam et al., 2010; Nermoen et al., 2013). For the Callovo -Oxfordian claystone the Biot coefficient is estimated to be in the range of 0.84 (Belmokhtar et al., 2018). Biot coefficient for gas-bearing tight sandstone is estimated at  $\alpha \approx 0.38$  (Selvadurai, 2019). Other estimates for a variety of rocks encountered in a coal mining setting are also given by Chen et al. (2019).

## Acknowledgement

The work described in the paper was supported by a Discovery Research Grant awarded by the Natural Sciences and Engineering Research Council of Canada. This study is part of the In situ Stimulation and Circulation (ISC) project established by the Swiss Competence Center for Energy Research-Supply of Electricity (SCCER-SoE) with the support of Innosuisse. The authors are also grateful to Professor Eduardo Alonso (UPC, Spain), Professor Lyesse Laloui (EPFL, Switzerland), Professor Florian Amman (RWTH, Germany), Professor Martin Mazurek (University

314 of Bern, Switzerland), Dr. Stratis Vmvoris (NAGRA, Switzerland), Professor Christian David (Université Cergy-  
315 Pontoise, France), Dr. Jonny Rutqvist (LBNL, USA), Dr. Farid Laouafa (INERIS, France) and Dr. Son Nguyen  
316 (CNSC, Canada) and Professor R.W. Zimmerman (Imperial College, UK) for helpful comments. The authors grate-  
317 fully acknowledge the comments made by Dr. Joseph Doetsch, Institute of Geophysics, Department of Earth Sciences  
318 ETH Zurich, which led to improvements in the presentation. The authors, however, are entirely responsible for the  
319 statements and conclusions presented in the paper. Finally, the authors are grateful to the reviewers for their highly  
320 constructive comments that led to improvements in the presentation.
